

# Lecture 7: Linear Time Selection

(CLRS 9)

September 16, 2003

## 1 Quick-Sort Review

- The last two lectures we have considered Quick-Sort:
  - Divide  $A[1..n]$  (using PARTITION) into subarrays  $A' = A[1..q-1]$  and  $A'' = A[q+1..n]$  such that all elements in  $A''$  are larger than  $A[q]$  and all elements in  $A'$  are smaller than  $A[q]$ .
  - Recursively sort  $A'$  and  $A''$ .
- We discussed how split point  $q$  produced by PARTITION only depends on last element in  $A$
- We discussed how randomization can be used to get good expected partition point.
- Analysis:
  - Best case ( $q = n/2$ ):  $T(n) = 2T(n/2) + \Theta(n) \Rightarrow T(n) = \Theta(n \log n)$ .
  - Worst case ( $q = 1$ ):  $T(n) = T(1) + T(n-1) + \Theta(n) \Rightarrow T(n) = \Theta(n^2)$ .
  - Expected case for randomized algorithm:  $\Theta(n \log n)$

## 2 Selection

- If we could find element  $e$  such that  $rank(e) = n/2$  (the *median*) in  $O(n)$  time we could make quick-sort run in  $\Theta(n \log n)$  time worst case.
    - We could just exchange  $e$  with last element in  $A$  in beginning of PARTITION and thus make sure that  $A$  is always partition in the middle
  - We will consider a more general problem than finding the median:
    - Selection problem: Compute SELECT( $i$ )
- SELECT( $i$ ) is the  $i$ 'th element in the sorted order of elements
- Note: We do not require that we sort to find SELECT( $i$ )
  - Note: SELECT(1)=minimum, SELECT( $n$ )=maximum, SELECT( $n/2$ )=median

Note:

- \* The trick is that we only recurse on one side.
- \* In the worst case the algorithm runs in  $T(n) = T(n-1) + n = \Theta(n^2)$  time.
- \* We could use randomization to get good expected partition.
- \* Even if we just always partition such that a constant fraction ( $\alpha < 1$ ) of the elements are eliminated we get running time  $T(n) = T(\alpha n) + n = n \sum_{i=0}^{\log n} \alpha^i = \Theta(n)$ .
- It turns out that we can modify the algorithm and get  $T(n) = \Theta(n)$  in the worst case
  - The idea is to find a split element  $q$  such that we always eliminate a fraction of the elements:

**SELECT( $i$ )**

- \* Divide  $n$  elements into groups of 5
- \* Select median of each group ( $\Rightarrow \lceil \frac{n}{5} \rceil$  selected elements)
- \* Use SELECT recursively to find median  $q$  of selected elements
- \* Partition *all* elements based on  $q$

$\xleftarrow{k} \quad \xrightarrow{n-k}$

- \* Use SELECT recursively to find  $i$ 'th element
  - If  $i \leq k$  then use SELECT( $i$ ) on  $k$  elements
  - If  $i > k$  then use SELECT( $i - k$ ) on  $n - k$  elements

- If  $n'$  is the maximal number of elements we recurse on in the last step of the algorithm the running time is given by  $T(n) = \Theta(n) + T(\lceil \frac{n}{5} \rceil) + \Theta(n) + T(n')$
- Estimation of  $n'$ :
  - Consider the following figure of the groups of 5 elements
    - \* An arrow between element  $e_1$  and  $e_2$  indicates that  $e_1 > e_2$
    - \* The  $\lceil \frac{n}{5} \rceil$  selected elements are drawn solid ( $q$  is median of these)
    - \* Elements definitely  $> q$  are indicated with box

- Number of elements  $> q$  is *larger* than  $3(\frac{1}{2}\lceil\frac{n}{5}\rceil - 2) \geq \frac{3n}{10} - 6$ 
  - \* We get 3 elements from each of  $\frac{1}{2}\lceil\frac{n}{5}\rceil$  columns except possibly the one containing  $q$  and the last one.

- Similarly the number of elements definitely  $< q$  is *larger* than  $\frac{3n}{10} - 6$

$\Downarrow$

We recurse on at most  $n' = n - (\frac{3n}{10} - 6) = \frac{7}{10}n + 6$  elements

- So  $\text{SELECTION}(i)$  runs in time  $T(n) = \Theta(n) + T(\lceil\frac{n}{5}\rceil) + T(\frac{7}{10}n + 6)$
- Solution to  $T(n) = n + T(\lceil\frac{n}{5}\rceil) + T(\frac{7}{10}n + 6)$ :
  - Guess  $T(n) \leq cn$
  - Induction:

$$\begin{aligned}
 T(n) &= n + T(\lceil\frac{n}{5}\rceil) + T(\frac{7}{10}n + 6) \\
 &\leq n + c \cdot \lceil\frac{n}{5}\rceil + c \cdot (\frac{7}{10}n + 6) \\
 &\leq n + c\frac{n}{5} + c + \frac{7}{10}cn + 6c \\
 &= \frac{9}{10}cn + n + 7c \\
 &\leq cn
 \end{aligned}$$

If  $7c + n \leq \frac{1}{10}cn$  which can be satisfied (e.g. true for  $c = 20$  if  $n > 140$ )

- Note: It is important that we chose every 5'th element, not all other choices will work (homework).
