

XSLT

CPS 116

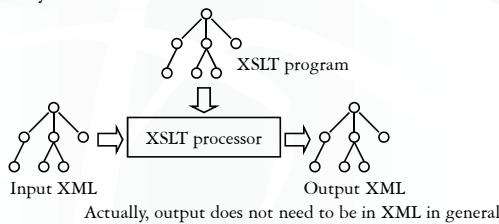

Introduction to Database Systems

Announcements (October 25)²

- ❖ Homework #3 due in 1½ weeks
 - Start early!
- ❖ Project milestone #2 due in 2 weeks

XSLT

- ❖ XML-to-XML rule-based transformation language
 - Used most frequently as a stylesheet language
 - An XSLT program is an XML document itself
 - Current version is 2.0; W3C recommendation since January 2007

XSLT program

- ❖ An XSLT program is an XML document containing
 - Elements in the <xsl:> namespace
 - Elements in user namespace
- ❖ The result of evaluating an XSLT program on an input XML document = the XSLT document where each <xsl:> element has been replaced with the result of its evaluation
- ❖ Basic ideas
 - Templates specify how to transform matching input nodes
 - Structural recursion applies templates to input trees recursively
- ❖ Uses XPath as a sub-language

XSLT elements

- ❖ Element describing transformation rules
 - <xsl:template>
- ❖ Elements describing rule execution control
 - <xsl:apply-templates>
 - <xsl:call-template>
- ❖ Elements describing instructions
 - <xsl:if>, <xsl:for-each>, <xsl:sort>, etc.
- ❖ Elements generating output
 - <xsl:value-of>, <xsl:attribute>, <xsl:copy-of>, <xsl:text>, etc.

XSLT example

- ❖ Find titles of books authored by “Abiteboul”

```
<?xml version="1.0"?>
<xsl:stylesheet
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  version="2.0">
<xsl:template match="book[author='Abiteboul']">
  <booktitle>
    <xsl:value-of select="title"/>
  </booktitle>
</xsl:template>
</xsl:stylesheet>
```
- ❖ Not quite; we will see why later

<xsl:template>

```
7 <xsl:template match="book[author='Abiteboul']">  
  <booktitle>  
    <xsl:value-of select="title"/>  
  </booktitle>  
</xsl:template>
```

- ❖ <xsl:template match="*match_expr*"> is the basic XSLT construct describing a transformation rule
 - *match_expr* is an XPath-like expression specifying which nodes this rule applies to
- ❖ <xsl:value-of select="*xpath_expr*" /> evaluates *xpath_expr* within the context of the node matching the template, and converts the result sequence to a string
- ❖ <booktitle> and </booktitle> simply get copied to the output for each node match

Template in action

```
8 <xsl:template match="book[author='Abiteboul']">  
  <booktitle>  
    <xsl:value-of select="title"/>  
  </booktitle>  
</xsl:template>
```

Example XML fragment

```
<book ISBN="ISBN-10" price="80.00">  
  <title>Foundations of Databases</title>  
  <author>Abiteboul</author>  
  <author>Hull</author>  
  <author>Vianu</author>  
  <publisher>Addison Wesley</publisher>  
  <year>1995</year>  
  <section></section>  
</book>  
<book ISBN="ISBN-20" price="40.00">  
  <title>A First Course in Databases</title>  
  <author>Ulman</author>  
  <author>Widom</author>  
  <publisher>Prentice-Hall</publisher>  
  <year>2002</year>  
  <section></section>  
</book>
```

Template applies

<booktitle>

Foundations of Databases

</booktitle>

Template does not apply;
default behavior is to process the
node recursively and print out all
text nodes

A First Course in Databases
Ulman
Widom
Prentice-Hall
2002
--

Removing the extra output

- ❖ Add the following template:

```
<xsl:template match="text()|@*"/>
```
- ❖ This template matches all text and attributes
- ❖ XPath features
 - `text()` is a node test that matches any text node
 - `@*` matches any attribute
 - `|` means “or” in XPath
- ❖ Body of the rule is empty, so all text and attributes become empty string
 - This rule effectively filters out things not matched by the other rule

<xsl:attribute>

- ❖ Again, find titles of books authored by “Abiteboul”; but make the output look like `<book title="booktitle"/>`

```
10 ...  
<xsl:template match="book[author='Abiteboul']">  
  <book title="{normalize-space(title)}"/>  
</xsl:template>  
... ...
```

A more general method

```
... ...  
<xsl:template match="book[author='Abiteboul']">  
  <book>  
    <xsl:attribute name="title">  
      <xsl:value-of select="normalize-space(title)"/>  
    </xsl:attribute>  
  </book>  
</xsl:template>      <xsl:attribute name="attr">body</xsl:attribute>  
... ...           adds an attributed named attr with value body to the  
parent element in the output
```

<xsl:copy-of>

- ❖ Another slightly different example: return (entire) books authored by “Abiteboul”

```
<?xml version="1.0"?>  
<xsl:stylesheet  
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"  
  version="2.0">  
  <xsl:template match="text()|@*"/>  
  <xsl:template match="book[author='Abiteboul']">  
    <xsl:copy-of select="."/>  
  </xsl:template>  
</xsl:stylesheet>
```
- ❖ <xsl:copy-of select="*xpath_expr*" /> copies the entire contents (including tag structures) of the node-set returned by *xpath_expr* to the output

Formatting XML into HTML

- ❖ Example templates to
 - Render a book title in italics in HTML
 - Render the authors as a comma-separated list
- ❖ Example templates to
 - <xsl:template match="book/title">
 <i><xsl:value-of select="normalize-space(.)"/></i>
</xsl:template>
 - <xsl:template match="book/author[1]">
 <xsl:value-of select="normalize-space(.)"/>
</xsl:template>
 - <xsl:template match="book/author[position()>1]">
 <xsl:text>, </xsl:text>
 <xsl:value-of select="normalize-space(.)"/>
</xsl:template>
- ❖ <xsl:text> allows precise control of white space in output

<xsl:apply-templates>

13

- ❖ Example: generate a table of contents
 - Display books in an HTML unordered list
 - For each book, first display its title, and then display its sections in an HTML ordered list
 - For each section, first display its title, and then display its subsections in an HTML ordered list
- ```
<xsl:template match="title">
 <xsl:value-of select="normalize-space(.)"/>
</xsl:template>
<xsl:template match="section">

 <xsl:apply-templates select="title"/>
 <xsl:apply-templates select="section"/>

</xsl:template>
 <xsl:apply-templates select="xpath_expr"/>
 applies templates recursively to the node-set
 returned by xpath_expr
```
- (Continue on next slide)

## Example continued

14

```
<xsl:template match="book">

 <xsl:apply-templates select="title"/>
 <xsl:apply-templates select="section"/>

</xsl:template>
<xsl:template match="bibliography">
 <html>
 <head><title>Bibliography</title></head>
 <body>
 <xsl:apply-templates select="book"/>
 </body>
 </html>
</xsl:template>
```

- ❖ One problem remains

- Even if a book or a section has no sections, we will still generate an empty <ol></ol> element

## <xsl:if>

15

- ❖ A fix using <xsl:if>: replace  
 <ol><xsl:apply-templates select="section"/></ol>  
 with  
 <xsl:if test="section">  
 <ol><xsl:apply-templates select="section"/></ol>
 </xsl:if>
- ❖ The body of <xsl:if test="*xpath\_cond*"> is processed only if *xpath\_cond* evaluates to true

## Output control

16

- ```
<xsl:output method="html" indent="yes"/>
```
- ❖ Specifies that output
 - Will be HTML
 - Will be indented to make reading easier
 - ❖ Other possible method values include "text", "xml"
 - For XML output method, set
 omit-xml-declaration="yes"
 to suppress "<?xml ...?>" at the beginning of the output

White space control

17

- ❖ White space is everywhere in XML

```
... ...
<book ISBN="ISBN-10" price="80.00">...
  <title>...
    Foundations of Databases...
  </title>...
  ...
  □ "..." goes into a text node (assuming no DTD)
  □ "...Foundations of Databases..." goes into another text node
```
- ❖ Specify <xsl:strip-space elements="*"/> to remove text nodes (under any element) containing only white space
- ❖ To strip leading and trailing white space and replace any sequence of white space characters by a single space, specify
<xsl:template match="text()">
 <xsl:value-of select="normalize-space()"/>
</xsl:template>

<xsl:for-each>

18

- ❖ <xsl:for-each select="*xpath_expr*">
 body
</xsl:for-each>
 - Process *body* for each node in the node-set returned by *xpath_expr*
 - Processing context changes to the node being processed
- ❖ Another way to render authors as a comma-separated list
<xsl:template match="book">
 ...
 <xsl:for-each select="author">
 <xsl:if test="position()>1">, </xsl:if>
 <xsl:value-of select="normalize-space(.)"/>
 </xsl:for-each>
 ...
</xsl:template>

Named templates with parameters

19

- ❖ Define a generic template for rendering a list of things as a comma-separated list
 - Cannot use `match` because we do not know in advance the things to render

```
<xsl:template name="comma-separated-list">
  <xsl:param name="things-to-be-formatted"/>
  <xsl:for-each select="$things-to-be-formatted">
    <xsl:if test="position()>1">, </xsl:if>
    <xsl:value-of select="normalize-space(.)"/>
  </xsl:for-each>
</xsl:template>
```

Calling templates & passing parameters

20

- ❖ Use the generic template

```
<xsl:template match="book">
  <xsl:value-of select="normalize-space(title)"/>
  <xsl:text>: </xsl:text>
  <xsl:call-template name="comma-separated-list">
    <xsl:with-param name="things-to-be-formatted"
      select="author"/>
  </xsl:call-template>
  <br/>
</xsl:template>
```
- ❖ `<xsl:with-param name="para_name" select="xpath_expr">` evaluates `xpath_expr` and passes its result as the value of the parameter `para_name`
- ❖ `<xsl:call-template>` invokes the named template without changing the context

XSLT summary

21

- ❖ Used often as a stylesheet language, but can be considered a query language too
 - Grouping in XSLT 2.0 (`<xsl:for-each-group>`)
 - Very expressive, with full recursion
 - Cannot be replaced by XQuery?
 - Well, XQuery supports user-defined functions, which can be recursive
 - Easily non-terminating, difficult to optimize
 - Cannot replace XQuery
- ❖ So many features, so little time! ☺

Review

22

- ❖ XML: tree (or graph)-structured data
- ❖ DTD: simple schema for XML
 - Well-formed XML: syntactically correct
 - Valid XML: well-formed and conforms to a DTD
- ❖ XPath: path expression language for XML
 - An XPath expression selects a list of nodes in an XML document
 - Used in other languages
- ❖ XQuery: SQL-like query language for XML
 - FLWOR expression, quantified expression, aggregation, etc.
- ❖ XSLT: stylesheet language for XML, in XML
 - Transforms input XML by applying template rules recursively on the structure of input XML
