### Announcements

- Reading and RQ 11 due next time
- APT 4 out due next Thursday
- Today:
  - More on Lists
  - Solving APTs with: while True
  - Coming more ways to process data
  - Exam 1 back next time

compsci101 fall 2017

2

# Problem: Find the location of first adjacent duplicate word

- "This is a story story about a girl with a red hood..."
- Return 3 as the location of the first word that has a duplicate adjacent word (start at 0)

### Seven Steps – Step 1 work example by hand

- This is a story story about a girl ...
- This is a story story about a girl ...
- This is a story story about a girl ...
- This is a story story about a girl ...
- Step 2 write down what you did
- Step 3 generalize, special cases
- Step 4 work another example

### Seven Steps – Step 1 work example by hand

- This is a story story about a girl ... Position 0
- This <u>is a story story about a girl</u> ... Position 1
- This is <u>a story</u> story about a girl ... Position 2
- This is a story story about a girl ... Position 3

Return 3

- Step 2 write down what you did
- Step 3 generalize, special cases
- Step 4 work another example

#### APT: Pikachu

#### **Problem Statement**

Pikachu is a well-known character in the Pokemon anime series. Pikachu can speak, but only 3 syllables: "pi", "ka", and "chu". Therefore Pikachu can only pronounce strings that can be created as a concatenation of one or more syllables he can pronounce. For example, he can pronounce the words "pikapi" and "pikachu".

You are given a String word. Your task is

to check whether Pikachu can pronounce the string. If the string can be produced by concatenating copies of the strings "pi", "ka", and "chu", return "YES" (quotes for clarity). Otherwise, return "NO".

Specification

filename: Pikachu.py

word, a String

# you write code here

return String based on parameter

def check(word):

compsci101 fall 2017

compaction fair 2017

# APT: Pikachu

### APT NameGroup

#### **APT: NameGroup**

#### **Problem Statement**

You are given a string of names called **names**, two additional names, called **one** and **two**, and a number called **space**. Your task is to figure out if the two names are in the string names with one first and then two and exactly "space" names between them. Neither name one or two can be in the names between them, and they must be different names. A **namegroup** is then a string of the name one, followed by the names in the space and then name two, all separated by a space. If this is true, return the first such namegroup string found. Otherwise return an empty string.

#### Specification

filename: NameGroup.py

def calculate(names, one, two, space):

names is a String of names separated by blanks, one and two are names, returns a string of names that starts with one and ends with two and has "space" names between them. Neither one nor two can be in the spacing. one cannot equal two. Otherwise returns ""

# you write code here

## APT NameGroup

1. "joe moe fred gus sam ted bo tom" "joe" "ted" 4

Returns "joe moe fred gus sam ted"

There is a name group that starts with joe, ends with ted and has 4 names between them.

2. "a b" "a" "b" 0
Returns: "a b"
There is a name group that starts with a, ends with b and has 0 names between them.

3. "a b c d b f g a b c d e f g a b c" "b" "g" 4
Returns: "b c d e f g"
Note that "b c d b f g" is not a name group since it contains b in the inner part. However, there is a valid name group, "b c d e f g", with no b nor g it.

                                                                  22
```

# Creating a list

21

23

• Given a list of numbers, create a second list of every number squared.

```
nums = [8, 3, 5, 4, 1]
sqnums = []
for v in nums:
    sqnums.append(v*v)
print sqnums
```

[64, 9, 25, 16, 1]

# More on List operations

- Previous page
  - nameOfList "dot" function (parameter)
    sqnums.append(v\*v)
- See list operations on next page
- Mutator vs hybrid vs return
  - Mutator changes the list (no return value)
  - Hybrid changes list and returns value
  - Return returns value, no change to list

### List operations from book

Method	Parameters	Result	Description
append	item	mutator	Adds a new item to the end of a list
insert	position, item	mutator	Inserts a new item at the position given
pop	none	hybrid	Removes and returns the last item
pop	position	hybrid	Removes and returns the item at position
sort	none	mutator	Modifies a list to be sorted
reverse	none	mutator	Modifies a list to be in reverse order
index	item	return idx	Returns the position of first occurrence of item
count	item	return ct	Returns the number of occurrences of item
remove	item	mutator compsci	Removes the first occurrence of item  101 fall 2017 25

### Problem

• Remove all negative numbers from list  $[4, -2, 5, 6, -3] \rightarrow [4, 5, 6]$ 

- Two ways
  - 1) return a new list with all negative numbers removed
  - 2) Modify a list to remove negative numbers

compsci101 fall 2017

            break
     value = numberlist[pos]
        if value < 0:
            numberlist.pop(pos)
        pos = pos + 1

somenums = [3, -1, 8, -5, -2, 6, 7]
removeNegatives3(somenums)</pre>
```

# Solving problems – APT MorseLikeCode

compsci101 fall 2017

- Compare find vs index
  - find with string returns -1 when not found
  - index with list CRASHES if not there!
  - You can't say: pos = alist.index("...")
  - Instead: if "..." in alist:

pos = alist.index("...")

• How to get started?
