Assignment 5 - How to play
Guess Word Cleverly

• Make it hard for the player to win!

• One way: Try hard words to guess?
  • "jazziest", "joking", "bowwowing"

• Another Way: Keep changing the word, sortof
Clever GuessWord

- **Current GuessWord:** Pick random secret word
  - User starts guessing

- **Can you change secret word?**
  - Yes, but must have letters in same place you have told user
    - Change consistent with all guesses
  - Make the user work harder to guess!

- **Discuss how next time**
VenmoTracker APT

- If Harry pays Sally $10.23,
  - "Harry:Sally:10.23" then Harry is out $10.23
APT: VenmoTracker

Problem Statement

You've been asked to help manage reports on how often people spend money using Venmo and whether they receive more money than they pay out. The input to your program is a list of transactions from Venmo. Each transaction has the same form:

"from:to:amount" where from is the name of the person paying amount dollars to the person whose name is to. The value of amount will be a valid float with at most two decimal places.

Return a list of strings that has each person who appears in any transaction with the net cash flow through Venmo that person has received. Every cent paid by the person to someone else is a pay-out and every cent received by a person is a pay-in. The difference between pay-out and pay-in is the cash flow received. This will be negative for each person who pays out more than they get via pay-in. See the examples for details.

The list returned should be sorted by name. Strings in the list returned are in the format "name:netflow" where the netflow is obtained by using `str(val)` where val is a float representing the net cash flow for that person.

Store money as int values, multiplying by 100 and dividing by 100 as needed for processing input and output, respectively.
APT Venmo Tracker Example

Examples

1. transactions: ["owen:susan:10", "owen:robert:10", "owen:drew:10"]
   returns ['drew:10.0', 'owen:-30.0', 'robert:10.0', 'susan:10.0']
   Owen pays everyone.
WOTO-1 VenmoTracker
Tools We’ve Used Before

• Keep track of every person we see
  • Use a list

• Keep track of net worth: money in, money out
  • Use a parallel list

• Maintain invariant: \( \text{names}[k] \leftrightarrow \text{money}[k] \)
  • \( k^{th} \) name has \( k^{th} \) money
Example:

[ "Harry:Sally:10.23", "Zeyu:Sally:20.00", "Sally:Barak:10.00"]

• How would we solve this?
• Could we use a parallel list?
• What would be the output?
Process Transaction
"Harry:Sally:10.23"

names = [ ]

money = [ ]
Put Harry in:
"Harry:Sally:10.23"

names = [ "Harry" ]

money = [ -10.23 ]
Put Sally in:
"Harry:Sally:10.23"

names = [ "Harry", "Sally" ]
    0    1

money = [ -10.23, 10.23 ]
    0    1
Process next transaction
"Zeyu:Sally:20.00"

names = [ “Harry”, “Sally” ]
0 1

money = [ -10.23, 10.23 ]
0 1
Put Zeyu in:
“Zeyu:Sally:20.00”

names = [ “Harry”, “Sally”, “Zeyu” ]
  0     1     2

money = [ -10.23, 10.23, -20.00 ]
  0     1     2
Update Sally in:
“Zeyu:Sally:20.00”

names = [ “Harry”, “Sally”, “Zeyu” ]
0 1 2

money = [ -10.23, 30.23, -20.00 ]
0 1 2
Process next Transaction
“Sally:Barak:10.00”

names = [ “Harry”, “Sally”, “Zeyu” ]
0 1 2

money = [ -10.23, 30.23, -20.00 ]
0 1 2
Update Sally in:
“Sally:Barak:10.00”

names = [ “Harry”, “Sally”, “Zeyu” ]

money = [ -10.23, 20.23, -20.00 ]
Add Barak in:
“Sally:Barak:10.00”

names = [ “Harry”, “Sally”, “Zeyu”, “Barak” ]
0 1 2 3

money = [ -10.23, 20.23, -20.00, 10.00 ]
0 1 2 3
Coding up Venmo

def networth(transactions):
    names = [ ]
    money = [ ]
    for trans in transactions:
        # split up trans
def networth(transactions):
    names = [ ]
    money = [ ]
    for trans in transactions:
        # split up trans
        data = trans.split(":")
        sender = data[0]
        receiver = data[1]
        amount = float(data[2])
Coding up Venmo

```python
if sender not in names:
    names.append(sender)
    money.append(0)

# similar if receiver not in names

# update money
indexSender = names.index(sender)
indexReceiver = names.index(receiver)
money[indexSender] -= amount
money[indexReceiver] += amount

# create output in correct format
```
Seen parallel lists before

- Solution outlined is reasonable, efficient?
  - How long does it take to find index of name?
  - It depends. Why?

- `list.index(elt)` or `elt in list` – fast?
  - What does "fast" mean? Relative to what?
Let’s try Dictionaries....
Example:

```
[ "Harry:Sally:10.23", "Zeyu:Sally:20.00", "Sally:Barak:10.00"]
```

- How would we solve this?
- Could we use a dictionary?
- What would be the output?
Example with Dictionary

1) "Harry:Sally:10.23"

- Start with empty dictionary, insert Harry
Example with Dictionary
1) "Harry:Sally:10.23"

- Insert Sally
Example with Dictionary
2) “Zeyu:Sally:20.00"

- Insert Zeyu, next update Sally

Harry → Sally: 10.23
Sally → Zeyu: -20.00
Example with Dictionary
2) “Zeyu:Sally:20.00"

- Update Sally

Zeyu → -20.00
Harry → -10.23
Sally → 30.23
Example with Dictionary
3) “Sally:Barak:10.00"

• Next Transaction – First update Sally

Zeyu → -20.00
Harry → -10.23
Sally → 30.23
Example with Dictionary

3) “Sally:Barak:10.00"

- Update Sally

Zeyu ➔ -20.00

Harry ➔ -10.23

Sally ➔ 20.23
Example with Dictionary
3) “Sally:Barak:10.00"

- Insert Barak

Zeyu ➔ -20.00
Harry ➔ -10.23
Sally ➔ 20.23
Barak ➔ 10.00
• List of (key, value) pairs
• [("Zeyu", -20.00), ("Harry", -10.23), ("Sally", 20.23), ("Barak", 10.00)]
Return Value

Zeyu -20.00
Harry -10.23
Sally 20.23
Barak 10.00

• [("Zeyu", -20.00), ("Harry", -10.23), ("Sally", 20.23), ("Barak", 10.00)]

Sort by name:
• [("Barak", 10.00), ("Harry", -10.23), ("Sally", 20.23), ("Zeyu", -20.00)]
Return Value

Zeyu: -20.00
Harry: -10.23
Sally: 20.23
Barak: 10.00

• ["Barak", 10.00), ("Harry", -10.23), ("Sally", 20.23), ("Zeyu", -20.00)]

Put in final format:
• ["Barak:10.00", "Harry:-10:23", "Sally:20.23", "Zeyu:-20.00"]
How would the code be different if we used a dictionary?
def networth(transactions):
    venmo = {}  
    for trans in transactions:
        # split up trans
```python
def networth(transactions):
    venmo = { }
    for trans in transactions:
        # split up trans
        data = trans.split(":")
        sender = data[0]
        receiver = data[1]
        amount = float(data[2])
```

---

Initialize dictionary

This part the same
if sender not in venmo:
    venmo[sender] = 0
# similar if receiver not in names
# update money
venmo[sender] -= amount
venmo[receiver] += amount
# create output in correct format

Code is shorter for dictionaries!
Code is faster for dictionaries!
You will need to finish it

• Now onto more on Dictionaries...
Dictionary Iteration (unordered!)

• **Iterate through keys:**
  • `for k in d:`
  • `for k in d.keys():`

• **Iterate through pairs:**
  • `for (k,v) in d.items():`
  • `for k,v in d.items():`
Sorting a list from dictionary - sorted()

```python
d = {'k': 3, 'h': 8, 'a': 12, 'd': 5}

x = sorted(d.keys())
y = sorted(d.values())
z = sorted(d.items())
```
Sorting a list from dictionary - sorted()

d = {'k': 3, 'h': 8, 'a': 12, 'd': 5}

x = sorted(d.keys())
x is ['a', 'd', 'h', 'k']
y = sorted(d.values())
y is [3, 5, 8, 12]
z = sorted(d.items())
z is [('a', 12), ('d', 5), ('h', 8), ('k', 3)]
WordFrequencies
Dictionary Example

• Let’s see an example that compares using a dictionary vs not using a dictionary
slowcount function
Short Code and Long Time

• See module WordFrequencies.py
  • Find # times each word in a list of words occurs
  • We have tuple/pair: word and word-frequency

```python
37 def slowcount(words):
38     pairs = [(w, words.count(w)) for w in set(words)]
39     return sorted(pairs)
```

• Think: How many times is `words.count(w)` called?
  • Why is `set(words)` used in list comprehension?
WordFrequencies with Dictionary

• If start with a million words, then...
• We look at a million words to count # "cats"
  • Then a million words to count # "dogs"
  • Could update with parallel lists, but still slow!
  • Look at each word once: dictionary!

• Key idea: use word as the "key" to find occurrences, update as needed
  • Syntax similar to `counter[k] += 1`
Using fastcount

• Update count if we've seen word before
  • Otherwise it's the first time, occurs once

```python
def fastcount(words):
    d = {}
    for w in words:
        if w in d:
            d[w] += 1
        else:
            d[w] = 1
    return sorted(d.items())
```
Using fastcount

- Update count if we've seen word before
- Otherwise it's the first time, occurs once

```python
def fastcount(words):
    d = {}
    for w in words:
        if w in d:
            d[w] += 1
        else:
            d[w] = 1
    return sorted(d.items())
```
Let’s run them and compare them!

• Run with Melville and observe time

• Run with Hawthorne and observe time
Let’s run them and compare them!

• Run with Melville and observe time
  • slowcount about 0.76 seconds
  • fastcount about 0.00 seconds

• Run with Hawthorne and observe time
  • slowcount about 14.6 seconds
  • fastcount about 0.03 seconds
Problem Solving

• Given Brodhead University. They have a basketball team.

• Data on players and how they did when playing against another team.

• List of lists named datalist
  • Each list has
    • school opponent name
    • player name
    • Points player scored
    • Whether game was ‘won’ or ‘lost’
Example: lists of 20 lists
dataList =

[['Duke', 'Bolton', '2', 'lost'],
 ['NCSU', 'Stone', '12', 'won'],
 ['Duke', 'Kreitz', '3', 'lost'],
 ['Duke', 'Pura', '6', 'lost'],
 ['GT', 'Dolgin', '4', 'lost'],
 ['WFU', 'Laveman', '20', 'won'],
 ['ECU', 'Parlin', '15', 'won'],
 ['UNC', 'Stone', '17', 'won'],
 ['UNC', 'Dolgin', '12', 'won'],
 ['UNC', 'Kreitz', '5', 'won'],
 ['Duke', 'Stone', '16', 'lost'],
 ['Duke', 'Laveman', '13', 'lost'],
 ['NCSU', 'Kreitz', '8', 'won'],
 ['NCSU', 'Dolgin', '18', 'won'],
 ['NCSU', 'Parlin', '13', 'won'],
 ['GT', 'Bolton', '7', 'lost'],
 ['GT', 'Stone', '9', 'lost'],
 ['WFU', 'Parlin', '14', 'won'],
 ['ECU', 'Laveman', '16', 'won'],
 ['ECU', 'Pura', '15', 'won'] ]
1) Write function `dictPlayerToNumGamesPlayedIn`

Build a dictionary of players mapped to number of games they have played in.

```python
def dictPlayerToNumGamesPlayedIn( datalist):
    # Code to implement the function
```

With previous example, player ‘Laveman’ would be mapped to 3 games
Woto-3 Players and Games Played in
def dictPlayerToNumGamesPlayedIn(datalist):
    d = {}
    for line in datalist:
        player = line[1]
        if player in d:
            d[player] += 1
        else:
            d[player] = 1
    return d
ANOTHER WAY: Write function dictPlayerToNumGamesPlayedIn

```python
def dictPlayerToNumGamesPlayedIn(datalist):
    d = {}
    for line in datalist:
        player = line[1]
        if player not in d:
            d[player] = 0
            d[player] += 1
    return d
```
2) Write function
playersPlayedInNumGames(number, datalist)
Calculate list of players who played in 3 or more games, give (player name, number of games played in), sort by player name

[('Dolgin', 3), ('Kreitz', 3), ('Laveman', 3), ('Parlin', 3), ('Stone', 4)]
2) Write function
playersPlayedInNumGames(number, datalist)

def playersPlayedInNumGames(number, datalist):
    d = dictPlayerToNumGamesPlayedIn(datalist)
    # build a list of tuples
    answer = [ ]
    for player in d.keys():
        if d[player] >= number:
            answer.append( (player, d[player] ) )
    return sorted(answer)
ANOTHER WAY  2) Write function
playersPlayedInNumGames(number, datalist)

```python
def playersPlayedInNumGames(number, datalist):
    d = dictPlayerToNumGamesPlayedIn(datalist)
    # build a list of tuples
    answer = []
    for (player, count) in d.items():
        if count >= number:
            answer.append( (player, count) )
    return sorted(answer)
```

11/3/22 Compsci 101, Fall 2022 64
Another way using a list comprehension! However, this is putting a lot in one long line. It may be better to break it up into steps as the previous two slides do. Less chance to make a mistake.

def playersPlayedInNumGames(number, datalist):
    d = dictPlayerToNumGamesPlayedIn(datalist)
    # build a list of tuples
    return sorted([[player, count) for (player,count) in d.items()] if count >= number] )
APT Family

APT: Family

Problem Statement

You have two lists: parents and children. The ith element in parents is the parent of the ith element in children. Count the number of grandchildren (the children of a person's children) for the person in the person variable.

Hint: Consider making a helper function that returns a list of a person's children.
Step 1: work an example by hand

```python
parents = ['Junhua', 'Anshul', 'Junhua', 'Anshul', 'Kerry']
children = ['Anshul', 'Jordan', 'Kerry', 'Paul', 'Kai']
person = 'Junhua'

Returns 3
```
Step 1: work an example by hand

```python
parents = ['Junhua', 'Anshul', 'Junhua', 'Anshul', 'Kerry']
children = ['Anshul', 'Jordan', 'Kerry', 'Paul', 'Kai']
person = 'Junhua'

Returns 3
```

- **First find the children of Junhua**
  - Loop over parents list
    - If name is Junhua add corresponding child to list
      - How do I do that? I need an index (parallel lists)
    - Kids are ['Anshul', 'Kerry']
  - For each kid:
    - Loop over parents list:
      - If name is kid’s name add their child to the list
        » How do I do that? I need an index (parallel lists)
    - ‘Anshul’s kids -> ‘Jordan’ and ‘Paul’
    - Kerry’s kids -> ‘Kai’
  - Return 3
Step 1: work an example by hand

They are the same!

They are the same!

Write a helper function!

• First find the children of Junhua
  • Loop over parents list
    • If name is Junhua add corresponding child to list
      – How do I do that? I need an index (parallel lists)
    • Kids are [‘Anshul’, ‘Kerry’]
  • For each kid:
    • Loop over parents list:
      – If name is kid’s name add their child to the list
        » How do I do that? I need an index (parallel lists)
      • ‘Anshul’s kids -> ‘Jordan’ and ‘Paul’
      • Kerry’s kids -> ‘Kai’
  • Return 3
Helper function

def childrenOf(parents, children, name):
    <missing code to traverse parallel lists>
    return list of name’s children
How to traverse parallel lists?

parents: ['Junhua', 'Anshul', 'Junhua', 'Anshul', 'Kerry']
children: ['Anshul', 'Jordan', 'Kerry', 'Paul', 'Kai']

index = 0
while index < len(parents):
    <do something>
    index += 1
How to traverse parallel lists?

parents: ['Junhua', 'Anshul', 'Junhua', 'Anshul', 'Kerry']
children: ['Anshul', 'Jordan', 'Kerry', 'Paul', 'Kai']

Iterate over the list – need a loop!
Need to access same position in each list
    - need an index

Use a while loop with an index!
How to traverse parallel lists?

parents: ['Junhua', 'Anshul', 'Junhua', 'Anshul', 'Kerry']
children: ['Anshul', 'Jordan', 'Kerry', 'Paul', 'Kai']

0             1             2            3            4

index = 0
while index < len(parents):
  <do something>
  index += 1          # update index
