

## Indexing: Part I

CPS 216  
Advanced Database Systems

---

---

---

---

---

---

---

---

## Announcements (February 3)

2

- ❖ Homework #1 due next Tuesday (February 8)
- ❖ No class next Thursday (February 10)
- ❖ Homework #2 will be assigned on the following Tuesday; meanwhile, use the time to think about course project!

---

---

---

---

---

---

---

---

## Basics

3

- ❖ Given a value, locate the record(s) with this value
  - SELECT \* FROM *R* WHERE *A* = *value*;
  - SELECT \* FROM *R*, *S* WHERE *R.A* = *S.B*;
- ❖ Other search criteria, e.g.
  - Range search  
SELECT \* FROM *R* WHERE *A* > *value*;
  - Keyword search

---

---

---

---

---

---

---

---

## Dense and sparse indexes

4

- ❖ Dense: one index entry for each search key value
- ❖ Sparse: one index entry for each block
  - Records must be clustered according to the search key

---

---

---

---

---

---

---

---

---

---

## Dense versus sparse indexes

5

- ❖ Index size
- ❖ Requirement on records
- ❖ Lookup
- ❖ Update

---

---

---

---

---

---

---

---

---

---

## Primary and secondary indexes

6

- ❖ Primary index
  - Created for the primary key of a table
  - Records are usually clustered according to the primary key
  - Can be sparse
- ❖ Secondary index
  - Usually dense
- ❖ SQL
  - PRIMARY KEY declaration automatically creates a primary index, UNIQUE key automatically creates a secondary index
  - Secondary index can be created on non-key attribute(s)  
 CREATE INDEX StudentGPAIndex ON Student (GPA);

---

---

---

---

---

---

---

---

---

---

# ISAM

7

❖ What if an index is still too big?

- Put a another (sparse) index on top of that!
- ☞ ISAM (Index Sequential Access Method), more or less

Example: look up 197

---

---

---

---

---

---

---

---

---

---

# Updates with ISAM

8

Example: insert 107  
Example: delete 129

❖ Overflow chains and empty data blocks degrade performance

- Worst case: most records go into one long chain

---

---

---

---

---

---

---

---

---

---

# B<sup>+</sup>-tree

9

- ❖ Disk-based: one node per block; large fan-out
- ❖ Balanced (more or less): good performance guarantee

---

---

---

---

---

---

---

---

---

---

## Sample B<sup>+</sup>-tree nodes

10

---

---

---

---

---

---

---

---

---

---

## B<sup>+</sup>-tree balancing properties

11

- ❖ All leaves at the same lowest level
- ❖ All nodes at least half full (except root)

	Max # pointers	Max # keys	Min # active pointers	Min # keys
Non-leaf	$f$	$f - 1$	$\lceil f/2 \rceil$	$\lceil f/2 \rceil - 1$
Root	$f$	$f - 1$	2	1
Leaf	$f$	$f - 1$	$\lfloor f/2 \rfloor$	$\lfloor f/2 \rfloor$

---

---

---

---

---

---

---

---

---

---

## Lookups

12

SELECT \* FROM R WHERE  $k = 179$ ;  
SELECT \* FROM R WHERE  $k = 32$ ;

---

---

---

---

---

---

---

---

---

---

## Range query

13

SELECT \* FROM R WHERE  $k > 32$  AND  $k < 179$ ;

---

---

---

---

---

---

---

---

## Insertion

14

❖ Insert a record with search key value 32

---

---

---

---

---

---

---

---

## Another insertion example

15

❖ Insert a record with search key value 152

---

---

---

---

---

---

---

---

## Node splitting

16

---

---

---

---

---

---

---

---

## More node splitting

17

- ❖ In the worst case, node splitting can "propagate" all the way up to the root of the tree (not illustrated here)
  - Splitting the root causes the tree to grow "up" by one level

---

---

---

---

---

---

---

---

## Deletion

18

- ❖ Delete a record with search key value 130

---

---

---

---

---

---

---

---

## Stealing from a sibling

19

---

---

---

---

---

---

---

---

## Another deletion example

20

❖ Delete a record with search key value 179

---

---

---

---

---

---

---

---

## Coalescing

21

- ❖ Deletion can "propagate" all the way up to the root of the tree (not illustrated here)
  - When the root becomes empty, the tree "shrinks" by one level

---

---

---

---

---

---

---

---

## Performance analysis

22

- ❖ How many I/O's are required for each operation?
  - $b$  (more or less), where  $b$  is the height of the tree
  - Plus one or two to manipulate actual records
  - Plus  $O(b)$  for reorganization (should be very rare if  $f$  is large)
  - Minus one if we cache the root in memory
- ❖ How big is  $b$ ?
  - Roughly  $\log_{\text{fan-out}} N$ , where  $N$  is the number of records
  - B<sup>+</sup>-tree properties guarantee that fan-out is least  $f/2$  for all non-root nodes
  - Fan-out is typically large (in hundreds)—many keys and pointers can fit into one block
  - A 4-level B<sup>+</sup>-tree is enough for typical tables

---

---

---

---

---

---

---

---

## B<sup>+</sup>-tree in practice

23

- ❖ Complex reorganization for deletion often is not implemented (e.g., Oracle, Informix)
- ❖ Most commercial DBMS use B<sup>+</sup>-tree instead of hashing-based indexes because B<sup>+</sup>-tree handles range queries

---

---

---

---

---

---

---

---

## The Halloween Problem

24

- ❖ Story from the early days of System R...

```
UPDATE Payroll
SET salary = salary * 1.1
WHERE salary >= 100000;
```

  - There is a B<sup>+</sup>-tree index on *Payroll(salary)*
  - The update never stopped (why?)
- ❖ Solutions?

---

---

---

---

---

---

---

---

## Building a B<sup>+</sup>-tree from scratch

25

### ❖ Naïve approach

- Start with an empty B<sup>+</sup>-tree
- Process each record as a B<sup>+</sup>-tree insertion

### ❖ Problem

---

---

---

---

---

---

---

---

## Bulk-loading a B<sup>+</sup>-tree

26

### ❖ Sort all records (or record pointers) by search key

- Just a few passes (assuming a big enough memory)
- More sequential I/O's

☞ Now we already have all leaf nodes!

### ❖ Insert each leaf node in order

- No need to look for the proper place to insert
- Only the rightmost path is affected; keep it in memory

---

---

---

---

---

---

---

---

## Other B<sup>+</sup>-tree tricks

27

### ❖ Compressing keys

- Head compression: factor out common key prefix and store it only once within an index node
  - Tail compression: choose the shortest possible key value during a split
  - In general, any order-preserving key compression
- ☞ Why does key compression help?

### ❖ Improving binary search within an index node

- Cache-aware organization
- Micro-indexing

### ❖ Using B<sup>+</sup>-tree to solve the phantom problem

---

---

---

---

---

---

---

---

## B<sup>+</sup>-tree versus ISAM

28

- ❖ ISAM is more static; B<sup>+</sup>-tree is more dynamic
- ❖ ISAM is more compact (at least initially)
  - Fewer levels and I/O's than B<sup>+</sup>-tree
- ❖ Overtime, ISAM may not be balanced
  - Cannot provide guaranteed performance as B<sup>+</sup>-tree does

---

---

---

---

---

---

---

---

## B<sup>+</sup>-tree versus B-tree

29

- ❖ B-tree: why not store records (or record pointers) in non-leaf nodes?
  - These records can be accessed with fewer I/O's
- ❖ Problems?

---

---

---

---

---

---

---

---

## Coming up next

30

- ❖ Other tree-based indexes: R-trees and variants, GiST
- ❖ Hashing-based indexes: extensible hashing, linear hashing, etc.
- ❖ Text indexes: inverted-list index, suffix arrays

---

---

---

---

---

---
