# Indexing: Part II 

CPS 216
Advanced Database Systems

## R-tree insertion

Insert $R_{9}$ into R -tree

* Start from the root
$*$ Pick a region containing $R_{9}$ and follow the child pointer
- If none contains $R_{9}$, pick one and grow it to contain $R_{9}$
- Pick the one that requires the least enlargement (why?)

## Announcements (February 8)

* Homework \#1 due today
* No class this Thursday (February 10)
* Reading assignments this week
- Generalized search trees (due next Tuesday)
- "The" Google paper (due next Thursday)

## R-tree lookup

* Which ranges contain me?

Problem: search may go down many paths

- Because regions may overlap
- No performance guarantee like B-tree

## R-tree insertion: split

* If a node is too full, split

* Try to minimize the total area of bounding boxes
- Exhaustive: try all possible splits
- Quadratic: "seed" with the most wasteful pair; iteratively assign regions with strongest "preference"
- Linear: "seed" with distant regions; iteratively assign others as Quadratic

## R-tree insertion: split (cont'd)

* Split could propagate all the way up to the root (not shown in this example)

$\mathrm{R}^{+}$-tree
* Problem with R-tree
- Regions may overlap
- Search may go down many paths
* $\mathrm{R}^{+}$-tree (Sellis et al., VLDB 1987)
- Regions in non-leaf nodes do not overlap
- Search only goes down one path
- Duplicate items in leaves
- But an insertion must now go down many paths!
- $R$ must be inserted into all $\mathrm{R}^{+}$-tree leaves whose bounding boxes overlap with $R$
- A bigger tree
$\mathrm{R}^{*}$-tree
* R-tree

- Always tries to minimize the area of bounding boxes
- Quadratic splitting algorithm encourages small seeds and possibly long and narrow bounding boxes
* R*-tree (Beckmann et al., SIGMOD 1990)
- Consider other criteria, e.g.
- Minimize overlap between bounding boxes
- Minimize the margin (perimeter length) of a bounding box
- Forced reinserts
- When a node overflows, reinsert "outer" entries
- They may be picked up by other nodes, thus saving a split

## Review

Tree-structured indexes

- ISAM
- B-tree and variants
- R-tree and variants
- Can we generalize? GiST!

## Indexing user-defined data types

* Specialized indexes (ABCDEFG trees...)
- Redundant code: most trees are very similar
- Concurrency control and recovery especially tricky to get right
* Extensible B-trees and R-trees
- Examples: B-trees in Berkeley DB, B- and R-trees in Informix
- User-defined compare() function
- GiST (Generalized Search Trees)
- General (covers B-trees, R-trees, etc.)
- Easy to extend
- Built-in concurrency control and recovery

## Structure of GiST

Balanced tree of $\langle p, p t r\rangle$ pairs
$* p$ is a key predicate that holds for all objects found below $p$ tr

* Every node has between $k M$ and $M$ index entries...
- $k$ must be no more than $1 / 2$ (why?)
* Except root, which only needs at least two children
* All leaves are on the same level
- User only needs to define what key predicates are

## Defining key predicates

* boolean Consistent(entry entry, predicate query)
- Return true if an object satisfying query might be found under entry * predicate Union(set<entry> entries)
- Return a predicate that holds for all objects found under entries
* real Penalty(entry entry 1, entry entry2)
- Return a penalty for inserting entry 2 into the subtree rooted at entry 1
* (set<entry>, set<entry>) PickSplit(set<entry> entries)
- Given $M+1$ entries, split it into two sets, each of size at least $k M$

## Index operations

* Search
- Just follow pointer whenever Consistent () is true
* Insert
- Descent tree along least increase in Penalty()
- If there is room in leaf, insert there; otherwise split according to PickSplit()
- Propagate changes up using Union()
* Delete
- Search for entry and delete it
- Propagate changes up using Union()
- On underflow
- If keys are ordered, can borrow/coalesce in B-tree style
- Otherwise, reinsert stuff in the node and delete the node

## GiST over $R\left(\mathrm{~B}^{+}\right.$-tree)

* Logically, keys represent ranges $[x, y)$
* Query: find keys that overlap with $[a, b)$
* Consistent(entry, $[a, b))$ : say entry has key $[x, y)$
- $x<b$ and $y>a$, i.e., overlap
* Union(entries): say entries $=\left\{\left[x_{i}, y_{i}\right)\right\}$
- $\left[\min \left(\left\{x_{i}\right\}\right), \max \left(\left\{y_{i}\right\}\right)\right)$
* Penalty $\left(\right.$ entry $_{1}$, entry $\left.y_{2}\right)$ : say they have keys $\left[x_{1}, y_{1}\right)$ and $\left[x_{2}, y_{2}\right)$
- $\max \left(y_{2}-y_{1}, 0\right)+\max \left(x_{1}-x_{2}, 0\right)$, except boundary cases
* PickSplit(entries)
- Sort entries and split evenly
* Plus a special Compare(entry, entry) for ordered keys

## Key compression

* Without compression, GiST would need to store a range instead of a single key value in order to support $\mathrm{B}^{+}$-tree
* Two extra methods: Compress/Decompress
* For $\mathrm{B}^{+}$-tree
- Compress(entry): say entry has key $[x, y)$
- $x$, assuming next entry starts with $y$, except boundary cases
- Decompress $(\langle x, p t r\rangle)$
- $[x, y)$, assuming next entry starts with $y$, except boundary cases

This compression is lossless: Decompress(Compress $(e))=e$

## GiST over $R^{2}$ (R-tree)

* Logically, keys represent bounding boxes
$*$ Query: find stuff that overlaps with a given box
Abusing notation a bit below...
* Consistent(key_box, query_box)
- key_box overlaps with query_box
* Union(boxes)
- Minimum bounding box of boxes
* Penalty $\left(b o x_{1}, b o x_{2}\right)$
- Area of $\operatorname{Union}\left(\left\{b o x_{1}, b o x_{2}\right\}\right)$ - area of $b o x_{1}$
* PickSplit(boxes)
- R-tree algorithms (e.g., minimize total area of bounding boxes)
* Compare(box, box)?

## GiST over $P(Z)$ (RD-tree)

* Logically, keys represent sets
* Queries: find all sets that intersect with a given set
* Consistent(key_set, query_set)
- key_set intersects with query_set
* Union(sets)
- Union of sets
* Penalty( set $_{1}$, set $_{2}$ )
- $\mid$ Union $\left(\left\{\right.\right.$ set $_{1}$, set $\left.\left._{2}\right\}\right)|-|$ set $_{1} \mid$
* PickSplit(sets)
- Much like R-tree (e.g., minimize total cardinality)
* Compare(set, set)?
* Compress/Decompress: bloomfilters, rangesets, etc
- Decompress(Compress(set)) ? set
- Lossy: Decompress(Compress(set)) $\supseteq$ set

## Next

* Hash-based indexing
* Text indexing
