

# Indexing: Part IV

CPS 216  
Advanced Database Systems

---

---

---

---

---

---

---

---

## Announcements (February 17)

2

- ❖ Homework #2 due in two weeks
- ❖ Reading assignments for this and next week
  - “The” query processing survey by Graefe
  - Due next Wednesday
- ❖ Midterm and course project proposal in three weeks

---

---

---

---

---

---

---

---

## Keyword search

3

The screenshot shows a search engine interface with several search results. The search query is "database AND search". The results include:

- The Internet Movie Database (IMDb)...
- ... Search the Internet Movie Database. For more search options, please visit Search central...
- Google... Images | G... try Search | Fr... lucky d Search | res | Lang...
- CPS 216: Advanced Database Systems (Fall 2001) Course Information Course Description / Time and Place / Books Resources: Staff...
- Association for Computing Machinery... nded in 1947, I is the world's educational and tific computing ty. Today, our bbers—...

At the bottom, there is a search bar containing the text "database AND search" and a "Search" button.

What are the documents containing both “database” and “search”?

---

---

---

---

---

---

---

---

## Keywords × documents

4

All keywords

All documents

Document 1    Document 2    Document 3    Document #

"a"	1	1	1	...	1
"cat"	1	1	0	...	0
"database"	0	0	1	...	0
"dog"	0	1	0	...	1
"search"	0	0	1	...	0
...	...	...	...	...	...

1 means keyword appears in the document  
0 means otherwise

- ❖ Inverted lists: store the matrix by rows
  - ❖ Signature files: store the matrix by columns
- With compression, of course!

---

---

---

---

---

---

---

---

---

---

## Inverted lists

5

- ❖ Store the matrix by rows
- ❖ For each keyword, store an inverted list
  - $\langle \text{keyword}, \text{doc-id-list} \rangle$
  - $\langle \text{"database"}, \{3, 7, 142, 857, \dots\} \rangle$
  - $\langle \text{"search"}, \{3, 9, 192, 512, \dots\} \rangle$
  - It helps to sort *doc-id-list* (why?)
- ❖ Vocabulary index on keywords
  - B<sup>+</sup>-tree or hash-based
- ❖ How large is an inverted list index?

---

---

---

---

---

---

---

---

---

---

## Using inverted lists

6

- ❖ Documents containing "database"
  - Use the vocabulary index to find the inverted list for "database"
  - Return documents in the inverted list
- ❖ Documents containing "database" AND "search"
- ❖ OR? NOT?

---

---

---

---

---

---

---

---

---

---

## What are “all” the keywords?

7

- ❖ All sequences of letters (up to a given length)?
  - ... that actually appear in documents!
- ❖ All words in English?
- ❖ Plus all phrases?
  - Alternative: approximate phrase search by proximity
- ❖ Minus all stop words
  - They appear in nearly every document; not useful in search
  - Example: a, of, the, it
- ❖ Combine words with common stems
  - They can be treated as the same for the purpose of search
  - Example: database, databases

---

---

---

---

---

---

---

---

## Frequency and proximity

8

- ❖ Frequency
  - $\langle \text{keyword}, \{ \langle \text{doc-id}, \text{number-of-occurrences} \rangle, \langle \text{doc-id}, \text{number-of-occurrences} \rangle, \dots \} \rangle$
- ❖ Proximity (and frequency)
  - $\langle \text{keyword}, \{ \langle \text{doc-id}, \langle \text{position-of-occurrence}_1, \text{position-of-occurrence}_2, \dots \rangle \rangle, \langle \text{doc-id}, \langle \text{position-of-occurrence}_1, \dots \rangle \rangle, \dots \} \rangle$
  - When doing AND, check for positions that are near

---

---

---

---

---

---

---

---

## Signature files

9

- ❖ Store the matrix by columns and compress them
- ❖ For each document, store a  $w$ -bit signature
- ❖ Each word is hashed into a  $w$ -bit value, with only  $s < w$  bits turned on
- ❖ Signature is computed by taking the bit-wise OR of the hash values of all words on the document

Does  $doc_3$  contain "database"?

$hash(\text{"database"}) = 0110$	$doc_1$ contains "database": 0110	"database"?
$hash(\text{"dog"}) = 1100$	$doc_2$ contains "dog": 1100	
$hash(\text{"cat"}) = 0010$	$doc_3$ contains "cat" and "dog": 1110	

- ☞ Some false positives; no false negatives

---

---

---

---

---

---

---

---

# Bit-sliced signature files

- ❖ Motivation
  - To check if a document contains a word, we only need to check the bits that are set in the word's hash value
  - So why bother retrieving all  $w$  bits of the signature?
- ❖ Instead of storing  $n$  signature files, store  $w$  bit slices
- ❖ Only check the slices that correspond to the set bits in the word's hash value
- ❖ Start from the sparse slices

doc	signature
1	000011100
2	000011100
3	000111100
4	011011100
...	...
$n$	000011100

↓                      ↓  
 Slice 7    ...    Slice 0  
 Bit-sliced signature files  
 Starting to look like an inverted list again!

---

---

---

---

---

---

---

---

---

---

# Inverted lists versus signatures

- ❖ Inverted lists better for most purposes (*TODS*, 1998)
- ❖ Problems of signature files
  - False positives
  - Hard to use because  $s$ ,  $w$ , and the hash function need tuning to work well
  - Long documents will likely have mostly 1's in signatures
  - Common words will create mostly 1's for their slices
  - Difficult to extend with features such as frequency, proximity
- ❖ Saving grace of signature files
  - Sizes are tunable
  - Good for lots of search terms
  - Good for computing similarity of documents

---

---

---

---

---

---

---

---

---

---

# Ranking result pages

- ❖ A single search may return many pages
  - A user will not look at all result pages
  - Complete result may be unnecessary
  - ☞ Result pages need to be ranked
- ❖ Possible ranking criteria
  - Based on content
    - Number of occurrences of the search terms
    - Similarity to the query text
  - Based on link structure
    - Backlink count
    - PageRank
  - And more...

---

---

---

---

---

---

---

---

---

---

## Textual similarity

13

- ❖ Vocabulary:  $\{w_1, \dots, w_n\}$
- ❖ IDF (Inverse Document Frequency):  $\{f_1, \dots, f_n\}$ 
  - $f_i = \log_2(\text{total \# of docs} / \text{\# of docs containing } w_i)$
- ❖ TF (Term Frequency):  $\{p_1, \dots, p_n\}$ 
  - $p_i = \text{\# of times } w_i \text{ appears on } p$
- ❖ Significance of words on page  $p$ :  $\{p_1 f_1, \dots, p_n f_n\}$
- ❖ Textual similarity between two pages  $p$  and  $q$  is defined to be  $\{p_1 f_1, \dots, p_n f_n\} \cdot \{q_1 f_1, \dots, q_n f_n\} = p_1 q_1 f_1^2 + \dots + p_n q_n f_n^2$ 
  - $q$  could be the query text

---

---

---

---

---

---

---

---

## Why weight significance by IDF?

14

---

---

---

---

---

---

---

---

## Problems with content-based ranking

15

- ❖ Many pages containing search terms may be of poor quality or irrelevant
  - Example: a page with just a line “search engine”
- ❖ Many high-quality or relevant pages do not even contain the search terms
  - Example: Google homepage
- ❖ Page containing more occurrences of the search terms are ranked higher; spamming is easy
  - Example: a page with line “search engine” repeated many times

---

---

---

---

---

---

---

---

## Backlink

16

- ❖ A page with more backlinks is ranked higher
- ❖ Intuition: Each backlink is a “vote” for the page’s importance

---

---

---

---

---

---

---

---

## Google’s PageRank

17

- ❖ Main idea: Pages pointed by high-ranking pages are ranked higher
  - Definition is recursive by design
  - Based on global link structure; hard to spam
- ❖ Naïve PageRank
  - $N(p)$ : number of outgoing links from page  $p$
  - $B(p)$ : set of pages that point to  $p$
  - $\text{PageRank}(p) = \sum_{q \in B(p)} (\text{PageRank}(q) / N(q))$
  - ☞ Each page  $p$  gets a boost of its importance from each page that points to  $p$
  - ☞ Each page  $q$  evenly distributes its importance to all pages that  $q$  points to

---

---

---

---

---

---

---

---

## Calculating naïve PageRank

18

- ❖ Initially, set all PageRank’s to 1; then evaluate  $\text{PageRank}(p) \leftarrow \sum_{q \in B(p)} (\text{PageRank}(q) / N(q))$  repeatedly until the values converge (i.e. a fixed point is reached)

$$\begin{bmatrix} n \\ m \\ a \end{bmatrix} = \begin{bmatrix} 0.5 & 0 & 0.5 \\ 0 & 0 & 0.5 \\ 0.5 & 1 & 0 \end{bmatrix} \begin{bmatrix} n \\ m \\ a \end{bmatrix}$$

$$\begin{bmatrix} n \\ m \\ a \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 0.5 \\ 1.5 \end{bmatrix}, \begin{bmatrix} 1.25 \\ 0.75 \\ 1 \end{bmatrix}, \begin{bmatrix} 1.125 \\ 0.5 \\ 1.375 \end{bmatrix}, \begin{bmatrix} 1.25 \\ 0.6875 \\ 1.0625 \end{bmatrix}, \dots, \begin{bmatrix} 1.2 \\ 0.6 \\ 1.2 \end{bmatrix}$$

---

---

---

---

---

---

---

---

# Random surfer model

- ❖ A random surfer
  - Starts with a random page
  - Randomly selects a link on the page to visit next
  - Never uses the “back” button
- ❖ PageRank( $p$ ) measures the probability that a random surfer visits page  $p$

---

---

---

---

---

---

---

---

# Problems with the naïve PageRank

- ❖ Dead end: a page with no outgoing links
  - A dead end causes all importance to “leak” eventually out of the Web
- ❖ Spider trap: a group of pages with no links out of the group
  - A spider trap will eventually accumulate all importance of the Web

---

---

---

---

---

---

---

---

# Practical PageRank

- ❖  $d$ : decay factor
- ❖ PageRank( $p$ ) =  $d \cdot \sum_{q \in B(p)} (\text{PageRank}(q) / N(q)) + (1 - d)$
- ❖ Intuition in the random surfer model
  - A surfer occasionally gets bored and jump to a random page on the Web instead of following a random link on the current page

---

---

---

---

---

---

---

---

## Google (1998)

22

- ❖ Inverted lists in practice contain a lot of context information

	Hit: 2 bytes	Relative Capitalization	font size		
In URL/title/meta tag	plain: cap:1	imp:3	position: 12		within the page
	fancy: cap:1	imp = 7	type: 4	position: 8	within the page
In anchor text	anchor: cap:1	imp = 7	type: 4	hash:4   pos: 4	within the anchor

URL associated with the anchor

- ❖ PageRank is not the final ranking
  - Type-weight: depends on the type of the occurrence
    - For example, large font weights more than small font
  - Count-weight: depends on the number of occurrences
    - Increases linearly first but then tapers off
  - For multiple search terms, nearby occurrences are matched together and a proximity measure is computed
    - Closer proximity weights more

---

---

---

---

---

---

---

---

---

---

---

---

## Suffix arrays (SODA, 1990)

23

- ❖ Another index for searching text
- ❖ Conceptually, to construct a suffix array for string  $S$ 
  - Enumerate all  $|S|$  suffixes of  $S$
  - Sort these suffixes in lexicographical order
- ❖ To search for occurrences of a substring
  - Do a binary search on the suffix array

---

---

---

---

---

---

---

---

---

---

---

---

## Suffix array example

24

$S = \text{mississippi}$       $q = \text{sip}$

Suffixes:	Sorted suffixes:	Suffix array:	
mississippi	i	10	
ississippi	ippi	7	
ssissippi	issippi	4	No need to store
sissippi	ississippi	1	the suffix strings;
issippi	mississippi	0	just store where
ssippi	⇨ pi	9	they start
sippi	ppi	8	
ippi	⇨ sippi	6	$O( q  \cdot \log  S )$
ppi	⇨ sissippi	3	
pi	ssippi	5	
i	ssissippi	2	

---

---

---

---

---

---

---

---

---

---

---

---

## One improvement

25

- ❖ Remember how much of the query string has been matched

$q = \text{sisterhood}$

low:  $\Rightarrow$  sissippi... Matched 3 characters

middle:  $\Rightarrow$  sisterhood... Start checking from the 4<sup>th</sup> character

high:  $\Rightarrow$  sistering... Matched 5 characters

---

---

---

---

---

---

---

---

## Another improvement

26

- ❖ Pre-compute the longest common prefix information between suffixes
  - For all (*low*, *middle*) and (*middle*, *high*) pairs that can come up in a binary search

$q = \text{sisterhood}$   $O(|q| + \log |S|)$

low:  $\Rightarrow$  sissippi... Matched 3 characters

middle:  $\Rightarrow$  sisterhood... Start checking from the 7<sup>th</sup> character

...  $\Rightarrow$  Matched 6 characters (pre-computed)

high:  $\Rightarrow$  sistering... Matched 6 characters

---

---

---

---

---

---

---

---

## Suffix arrays versus inverted lists

27

---

---

---

---

---

---

---

---

### Trie: a string index

- ❖ A tree with edges labeled by characters
- ❖ A node represents the string obtained by concatenating all characters along the path from the root

- ❖ Compact trie: replace a path without branches by a single edge labeled by a string

---

---

---

---

---

---

---

---

### Suffix tree

Index all suffixes of a large string in a compact trie

- ☞ Can support the same queries as a suffix array
- ❖ Internal nodes have fan-out  $\geq 2$  (except the root)
- ❖ No two edges out of the same node can share the same first character

To get linear space

- ❖ Instead of inlining the string labels, store pointers to them in the original string

---

---

---

---

---

---

---

---

### Patricia trie, Pat tree, String B-tree

A Patricia trie is just like a compact trie, but

- ❖ Instead of labeling each edge by a string, only label by the first character and the string length
- ❖ Leaves point to strings
- ☞ Faster search (especially for external memory) because of inlining of the first character
- ☞ But must validate answer at leaves for skipped characters

- ❖ A Pat tree indexes all suffixes of a large string in a Patricia trie
- ❖ A String B-tree uses a Patricia trie to store and compare strings in B-tree nodes

---

---

---

---

---

---

---

---

## Summary

- ❖ General tree-based string indexing tricks
  - Trie, Patricia trie, String B-tree
  - Good exercise: put them in a GiST! ☺
- ❖ Two general ways to index for substring queries
  - Index words: inverted lists, signature files
  - Index all suffixes: suffix array, suffix tree, Pat tree
- ❖ Web search and information retrieval go beyond substring queries
  - TF/IDF, PageRank, ...

---

---

---

---

---

---

---

---
