Climbing an Infinite Ladder

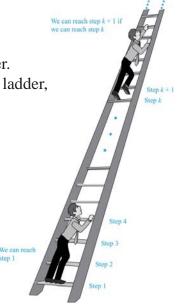

Suppose we have an infinite ladder:

1. We can reach the first rung of the ladder.

2. If we can reach a particular rung of the ladder, then we can reach the next rung.

From (1), we can reach the first rung. Then by applying (2), we can reach the second rung. Applying (2) again, the third rung. And so on. We can apply (2) any number of times to reach any particular rung, no matter how high up.

This example motivates proof by mathematical induction.

Principle of Mathematical Induction

Principle of Mathematical Induction: To prove that P(n) is true for all positive integers n, we complete these steps:

- Basis Step: Show that P(1) is true.
- *Inductive Step*: Show that $P(k) \rightarrow P(k+1)$ is true for all positive integers k.

To complete the inductive step, assuming the *inductive* hypothesis that P(k) holds for an arbitrary integer k, show that must P(k+1) be true.

Climbing an Infinite Ladder Example:

- BASIS STEP: By (1), we can reach rung 1.
- INDUCTIVE STEP: Assume the inductive hypothesis that we can reach rung k. Then by (2), we can reach rung k + 1.

Hence, $P(k) \rightarrow P(k+1)$ is true for all positive integers k. We can reach every rung on the ladder.

Important Points About Using Mathematical Induction

• Mathematical induction can be expressed as the rule of inference

$$(P(1) \land \forall k \ (P(k) \rightarrow P(k+1))) \rightarrow \forall n \ P(n),$$
 where the domain is the set of positive integers.

- In a proof by mathematical induction, we don't assume that P(k) is true for all positive integers! We show that if we assume that P(k) is true, then P(k+1) must also be true.
- Proofs by mathematical induction do not always start at the integer 1. In such a case, the basis step begins at a starting point *b* where *b* is an integer. We will see examples of this soon.

Remembering How Mathematical Induction Works

Consider an infinite sequence of dominoes, labeled 1,2,3, ..., where each domino is standing.

Let P(n) be the proposition that the nth domino is knocked over.

We know that the first domino is knocked down, i.e., P(1) is true.

We also know that if whenever the kth domino is knocked over, it knocks over the (k + 1)st domino, i.e, $P(k) \rightarrow P(k + 1)$ is true for all positive integers k.

Hence, all dominos are knocked over.

P(n) is true for all positive integers n.

Validity of Mathematical Induction

- Mathematical induction is valid because of the well ordering property, which states that every nonempty subset of the set of positive integers has a least element (*see Section* 5.2 *and Appendix* 1). Here is the proof:
 - Suppose that P(1) holds and $P(k) \rightarrow P(k+1)$ is true for all positive integers k.
 - Assume there is at least one positive integer n for which P(n) is false. Then the set S of positive integers for which P(n) is false is nonempty.
 - By the well-ordering property, S has a least element, say m.
 - We know that m can not be 1 since P(1) holds.
 - Since m is positive and greater than 1, m-1 must be a positive integer. Since m-1 < m, it is not in S, so P(m-1) must be true.
 - But then, since the conditional $P(k) \rightarrow P(k+1)$ for every positive integer k holds, P(m) must also be true. This contradicts P(m) being false.
 - Hence, P(n) must be true for every positive integer n.

Proving a Summation Formula by Mathematical Induction

Example: Show that: $\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$ **Solution:**

Note: Once we have this conjecture, mathematical induction can be used to prove it correct.

•

Proving a Summation Formula by Mathematical Induction

Example: Show that: $\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$

$$\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$$

prove it correct.

Solution:

- BASIS STEP: P(1) is true since 1(1+1)/2 = 1.
- INDUCTIVE STEP: Assume true for P(k).

The inductive hypothesis is $\sum_{i=1}^{k} i = \frac{k(k+1)}{2}$ Under this assumption,

$$1 + 2 + \dots + k + (k+1) = \frac{k(k+1)}{2} + (k+1)$$

$$= \frac{k(k+1) + 2(k+1)}{2}$$

$$= \frac{(k+1)(k+2)}{2}$$

Conjecturing and Proving Correct a Summation Formula

Example: Conjecture and prove correct a formula for the sum of the first n positive odd integers. Then prove your conjecture.

Solution: We have: 1 = 1, 1 + 3 = 4, 1 + 3 + 5 = 9, 1 + 3 + 5 + 7 = 16, 1+3+5+7+9=25.

- We can conjecture that the sum of the first n positive odd integers is n^2 ,

$$1+3+5+\cdots+(2n-1)=n^2$$
.

- We prove the conjecture is proved correct with mathematical induction.
- BASIS STEP: P(1) is true since $1^2 = 1$.
- INDUCTIVE STEP: $P(k) \rightarrow P(k+1)$ for every positive integer k.

Assume the inductive hypothesis holds and then show that P(k) holds has well.

Inductive Hypothesis:
$$1 + 3 + 5 + \dots + (2k - 1) = k^2$$

– So, assuming P(k), it follows that:

$$1+3+5+\cdots+(2k-1)+(2k+1)=[1+3+5+\cdots+(2k-1)]+(2k+1)$$

= $k^2+(2k+1)$ (by the inductive hypothesis)
= k^2+2k+1
= $(k+1)^2$

- Hence, we have shown that P(k + 1) follows from P(k). Therefore the sum of the first n positive odd integers is n^2 .

Conjecturing and Proving Correct a Summation Formula

Example: Conjecture and prove correct a formula for the sum of the first n positive odd integers. Then prove your conjecture.

Solution: We have: 1 = 1, 1 + 3 = 4, 1 + 3 + 5 = 9, 1 + 3 + 5 + 7 = 16, 1+3+5+7+9=25.

- We prove the conjecture is proved correct with mathematical induction.
- INDUCTIVE STEP: $P(k) \rightarrow P(k+1)$ for every positive integer k. Assume the inductive hypothesis holds and then show that P(k) holds has well
- So, assuming P(k), it follows that:

Proving Inequalities

Example: Use mathematical induction to $n < 2^n$ for all positive integers prove that n.

Proving Inequalities

Example: Use mathematical induction to prove that $n < 2^n$ for all positive integers n.

Solution: Let P(n) be the proposition that $n < 2^n$.

- BASIS STEP: P(1) is true since $1 < 2^1 = 2$.
- INDUCTIVE STEP: Assume P(k) holds, i.e., $k < 2^k$, for an arbitrary positive integer k.
- Must show that P(k + 1) holds. Since by the inductive hypothesis, $k < 2^k$, it follows that:

$$k+1 < 2^k + 1 \le 2^k + 2^k = 2 \cdot 2^k = 2^{k+1}$$

Therefore $n < 2^n$ holds for all positive integers n.

Proving Inequalities

Example: Use mathematical induction to prove that $2^n < n!$, for every integer $n \ge 4$.

Solution: Let P(n) be the proposition that $2^n < n!$.

- BASIS STEP: P(4) is true since $2^4 = 16 < 4! = 24$.
- INDUCTIVE STEP: Assume P(k) holds, i.e., $2^k < k!$ for an arbitrary integer $k \ge 4$. To show that P(k+1) holds:

$$2^{k+1} = 2 \cdot 2^k$$

 $< 2 \cdot k!$ (by the inductive hypothesis)
 $< (k+1)k!$
 $= (k+1)!$

Therefore, $2^n < n!$ holds, for every integer $n \ge 4$.

Note that here the basis step is P(4), since P(0), P(1), P(2), and P(3) are all false.

Proving Inequalities

Example: Use mathematical induction to prove that $2^n < n!$, for every integer $n \ge 4$.

Solution: Let P(n) be the proposition that $2^n < n!$.

Proving Divisibility Results

Example: Use mathematical induction to prove that $n^3 - n$ is divisible by 3, for every positive integer n.

Solution: Let P(n) be the proposition that $n^3 - n$ is divisible by 3.

Proving Divisibility Results

Example: Use mathematical induction to prove that $n^3 - n$ is divisible by 3, for every positive integer n.

Solution: Let P(n) be the proposition that $n^3 - n$ is divisible by 3.

- BASIS STEP: P(1) is true since $1^3 1 = 0$, which is divisible by 3.
- INDUCTIVE STEP: Assume P(k) holds, i.e., $k^3 k$ is divisible by 3, for an arbitrary positive integer k. To show that P(k+1) follows:

$$(k+1)^3 - (k+1) = (k^3 + 3k^2 + 3k + 1) - (k+1)$$

= $(k^3 - k) + 3(k^2 + k)$

By the inductive hypothesis, the first term $(k^3 - k)$ is divisible by 3 and the second term is divisible by 3 since it is an integer multiplied by 3. So by part (i) of Theorem 1 in Section 4.1, $(k+1)^3 - (k+1)$ is divisible by 3.

Therefore, $n^3 - n$ is divisible by 3, for every integer positive integer n.

Number of Subsets of a Finite Set

Example: Use mathematical induction to show that if S is a finite set with n elements, where n is a nonnegative integer, then S has 2^n subsets.

(Chapter 6 uses combinatorial methods to prove this result.)

Solution: Let P(n) be the proposition that a set with n elements has 2^n subsets.

- Basis Step: P(0) is true, because the empty set has only itself as a subset and $2^0 = 1$.
- Inductive Step: Assume P(k) is true for an arbitrary nonnegative integer k.

Number of Subsets of a Finite Set

Example: Use mathematical induction to show that if S is a finite set with n elements, where n is a nonnegative integer, then S has 2^n subsets.

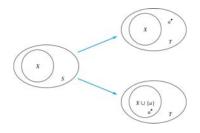

(Chapter 6 uses combinatorial methods to prove this result.)

Solution: Let P(n) be the proposition that a set with n elements has 2^n subsets.

- Basis Step:
- Inductive Step: Assume P(k) is true for an arbitrary nonnegative integer k.

Number of Subsets of a Finite Set

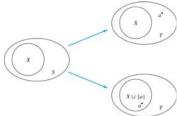

Inductive Hypothesis: For an arbitrary nonnegative integer k, every set with k elements has 2^k subsets.

Number of Subsets of a Finite Set

Inductive Hypothesis: For an arbitrary nonnegative integer k, every set with k elements has 2^k subsets.

- Let T be a set with k+1 elements. Then $T=S \cup \{a\}$, where $a \in T$ and $S=T-\{a\}$. Hence |T|=k.
- For each subset X of S, there are exactly two subsets of T, i.e., X and $X \cup \{a\}$.

• By the inductive hypothesis S has 2^k subsets. Since there are two subsets of T for each subset of S, the number of subsets of T is $2 \cdot 2^k = 2^{k+1}$.

Tiling Checkerboards

Inductive Hypothesis: Every $2^k \times 2^k$ checkerboard, for some positive integer k, with one square removed can be tiled using right triominoes.

Consider a 2^{k+1} ×2^{k+1} checkerboard with one square removed. Split this
checkerboard into four checkerboards of size 2^k ×2^k, by dividing it in half
in both directions.

- Remove a square from one of the four $2^k \times 2^k$ checkerboards. By the inductive hypothesis, this board can be tiled. Also by the inductive hypothesis, the other three boards can be tiled with the square from the corner of the center of the original board removed. We can then cover the three adjacent squares with a triominoe.
- Hence, the entire 2^{k+1} ×2^{k+1} checkerboard with one square removed can be

 tiled using right triominoes.

Tiling Checkerboards

Example: Show that every $2^n \times 2^n$ checkerboard with one square removed can be tiled using right triominoes.

A right triomino is an L-shaped tile which covers three squares at a time.

Solution: Let P(n) be the proposition that every $2^n \times 2^n$ checkerboard with one square removed can be tiled using right triominoes. Use mathematical induction to prove that P(n) is true for all positive integers n.

 BASIS STEP: P(1) is true, because each of the four 2 ×2 checkerboards with one square removed can be tiled using one right triomino.

- INDUCTIVE STEP: Assume that P(k) is true for every $2^k \times 2^k$ checkerboard, for some positive integer k.

An Incorrect "Proof" by Mathematical Induction

Example: Let P(n) be the statement that every set of n lines in the plane, no two of which are parallel, meet in a common point. Here is a "proof" that P(n) is true for all positive integers $n \ge 2$.

- BASIS STEP: The statement P(2) is true because any two lines in the plane that are not parallel meet in a common point.
- INDUCTIVE STEP: The inductive hypothesis is the statement that P(k) is true for the positive integer $k \ge 2$, i.e., every set of k lines in the plane, no two of which are parallel, meet in a common point.
- We must show that if P(k) holds, then P(k+1) holds, i.e., if every set of k lines in the plane, no two of which are parallel, $k \ge 2$, meet in a common point, then every set of k+1 lines in the plane, no two of which are parallel, meet in a common point.

An Incorrect "Proof" by Mathematical Induction

Inductive Hypothesis: Every set of k lines in the plane, where $k \ge 2$, no two of which are parallel, meet in a common point.

- Consider a set of k + 1 distinct lines in the plane, no two parallel. By the inductive hypothesis, the first k of these lines must meet in a common point p_1 . By the inductive hypothesis, the last k of these lines meet in a common point p_2 .
- If p_1 and p_2 are different points, all lines containing both of them must be the same line since two points determine a line. This contradicts the assumption that the lines are distinct. Hence, $p_1 = p_2$ lies on all k + 1 distinct lines, and therefore P(k + 1) holds. Assuming that $k \ge 2$, distinct lines meet in a common point, then every k + 1 lines meet in a common point.
- There must be an error in this proof since the conclusion is absurd. But where is the error?
 - Answer:

Guidelines: Mathematical Induction Proofs

Template for Proofs by Mathematical Induction

- Express the statement that is to be proved in the form "for all n ≥ b, P(n)" for a fixed integer b.
- 2. Write out the words "Basis Step." Then show that *P*(*b*) is true, taking care that the correct value of *b* is used. This completes the first part of the proof.
- 3. Write out the words "Inductive Step."
- 4. State, and clearly identify, the inductive hypothesis, in the form "assume that P(k) is true for an arbitrary fixed integer k > b."
- 5. State what needs to be proved under the assumption that the inductive hypothesis is true. That is, write out what P(k + 1) says.
- 6. Prove the statement P(k+1) making use the assumption P(k). Be sure that your proof is valid for all integers k with $k \ge b$, taking care that the proof works for small values of k, including k = b.
- 7. Clearly identify the conclusion of the inductive step, such as by saying "this completes the inductive step."
- 8. After completing the basis step and the inductive step, state the conclusion, namely that by mathematical induction, P(n) is true for all integers n with $n \ge b$.

An Incorrect "Proof" by Mathematical Induction

Inductive Hypothesis: Every set of k lines in the plane, where $k \ge 2$, no two of which are parallel, meet in a common point.

- Consider a set of k + 1 distinct lines in the plane, no two parallel. By the inductive hypothesis, the first k of these lines must meet in a common point p_1 . By the inductive hypothesis, the last k of these lines meet in a common point p_2 .
- If p_1 and p_2 are different points, all lines containing both of them must be the same line since two points determine a line. This contradicts the assumption that the lines are distinct. Hence, $p_1 = p_2$ lies on all k + 1 distinct lines, and therefore P(k + 1) holds. Assuming that $k \ge 2$, distinct lines meet in a common point, then every k + 1 lines meet in a common point.
- There must be an error in this proof since the conclusion is absurd. But where is the error?
 - **Answer**: $P(k) \rightarrow P(k+1)$ only holds for $k \ge 3$. It is not the case that P(2) implies P(3). The first two lines must meet in a common point p_1 and the second two must meet in a common point p_2 . They do not have to be the same point since only the second line is common to both sets of lines.
