

# Query Optimization

Introduction to Databases

CompSci 316 Spring 2017

**DUKE**  
COMPUTER SCIENCE

# Announcements (Mon., Mar. 27)

- Homework #3

- 3.3, 3.4, and 3.5 due Wednesday, March 29

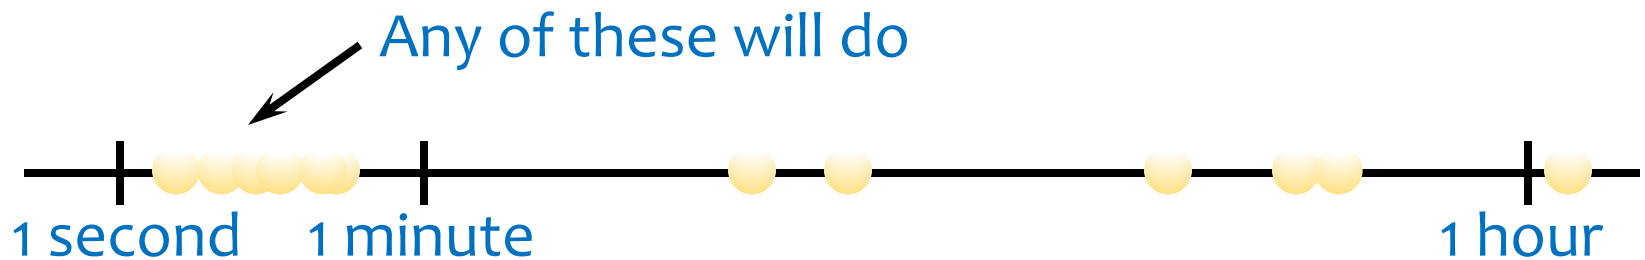

- Project

- Milestone 2 due today

- Submit both on sakai

# Query optimization (QO)

- One logical plan → “best” physical plan
- Questions
  - How to enumerate possible plans
  - How to estimate costs
  - How to pick the “best” one
- Often the goal is not getting the optimum plan, but instead avoiding the horrible ones. **Why?**
  - want to execute only one
  - need to estimate cost without executing the plan

# Steps for cost based QO

- Tasks:

1. Estimate the cost of individual operators -- done
2. Estimate the size of output of individual operators
3. Combine costs of different operators in a plan – next lecture
4. Efficiently search the space of plans

# Plan enumeration in relational algebra

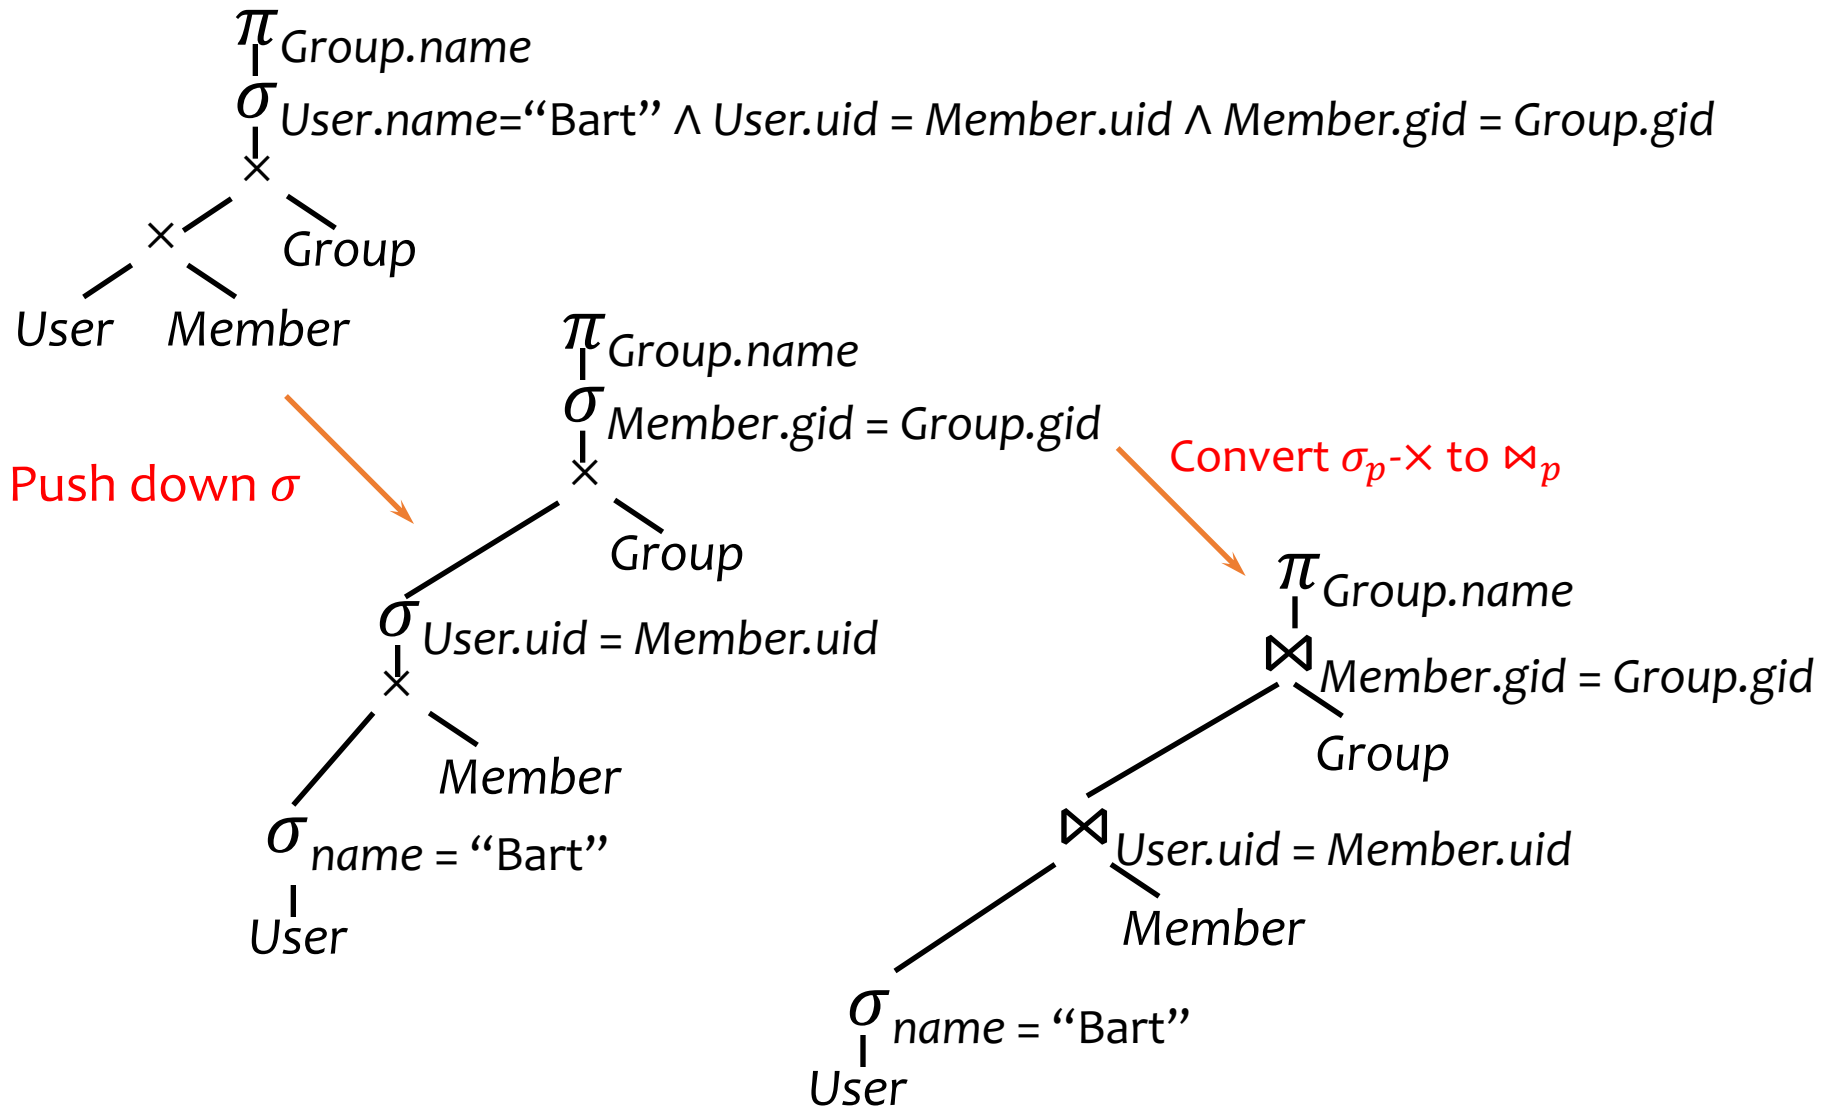

- Apply relational algebra equivalences
- ☞ Join reordering:  $\times$  and  $\bowtie$  are associative and commutative (except column ordering, but that is unimportant)

# More relational algebra equivalences

- Convert  $\sigma_p$ - $\times$  to/from  $\bowtie_p$ :  $\sigma_p(R \times S) = R \bowtie_p S$
- Merge/split  $\sigma$ 's:  $\sigma_{p_1}(\sigma_{p_2} R) = \sigma_{p_1 \wedge p_2} R$
- Merge/split  $\pi$ 's:  $\pi_{L_1}(\pi_{L_2} R) = \pi_{L_1} R$ , where  $L_1 \subseteq L_2$
- Push down/pull up  $\sigma$ :  
 $\sigma_{p \wedge p_r \wedge p_s}(R \bowtie_{p'} S) = (\sigma_{p_r} R) \bowtie_{p \wedge p'} (\sigma_{p_s} S)$ , where
  - $p_r$  is a predicate involving only  $R$  columns
  - $p_s$  is a predicate involving only  $S$  columns
  - $p$  and  $p'$  are predicates involving both  $R$  and  $S$  columns
- Push down  $\pi$ :  $\pi_L(\sigma_p R) = \pi_L(\sigma_p(\pi_{L L'} R))$ , where
  - $L'$  is the set of columns referenced by  $p$  that are not in  $L$
- Many more (seemingly trivial) equivalences...
  - Can be systematically used to transform a plan to new ones

# Relational query rewrite example

# Heuristics-based query optimization

- Start with a logical plan
- Push selections/projections down as much as possible (why/why not?)
  - Why? Reduce the size of intermediate results
  - Why not? May be expensive; maybe joins filter better
- Join smaller relations first, and avoid cross product (why/why not?)
  - Why? Reduce the size of intermediate results
  - Why not? Size depends on join selectivity too
- Convert the transformed logical plan to a physical plan (by choosing appropriate physical operators)

# SQL query rewrite

- More complicated—subqueries and views divide a query into nested “blocks”
  - Processing each block separately forces particular join methods and join order
  - Even if the plan is optimal for each block, it may not be optimal for the entire query
- **Unnest query:** convert subqueries/views to joins
- ☞ We can just deal with select-project-join queries
  - Where the clean rules of relational algebra apply

# SQL query rewrite example

User(uid, name)  
Member(uid, gid)

- SELECT name  
FROM User  
WHERE uid = ANY (SELECT uid FROM Member);
- SELECT name  
FROM User, Member  
WHERE User.uid = Member.uid;  
correct? wrong?
  - Wrong—consider two Bart's, each joining two groups
- SELECT name  
FROM (SELECT DISTINCT User.uid, name  
FROM User, Member  
WHERE User.uid = Member.uid);
  - Right—assuming User.uid is a key

# Dealing with correlated subqueries

- SELECT gid FROM **Group**  
 WHERE name LIKE 'Springfield%'  
 AND min\_size > (SELECT COUNT(\*) FROM Member  
 WHERE Member.gid = **Group.gid**);
 

Group(gid, name, min\_size)  
Member(uid, gid)
- SELECT gid  
 FROM Group, (SELECT gid, COUNT(\*) AS cnt  
 FROM Member GROUP BY gid) t  
 WHERE t.gid = Group.gid AND min\_size > t.cnt  
 AND name LIKE 'Springfield%';
 

What does this query output?

efficient? correct?
- New subquery is inefficient (it computes the size for *every* group)
- Suppose a group is empty?

# “Magic” decorrelation

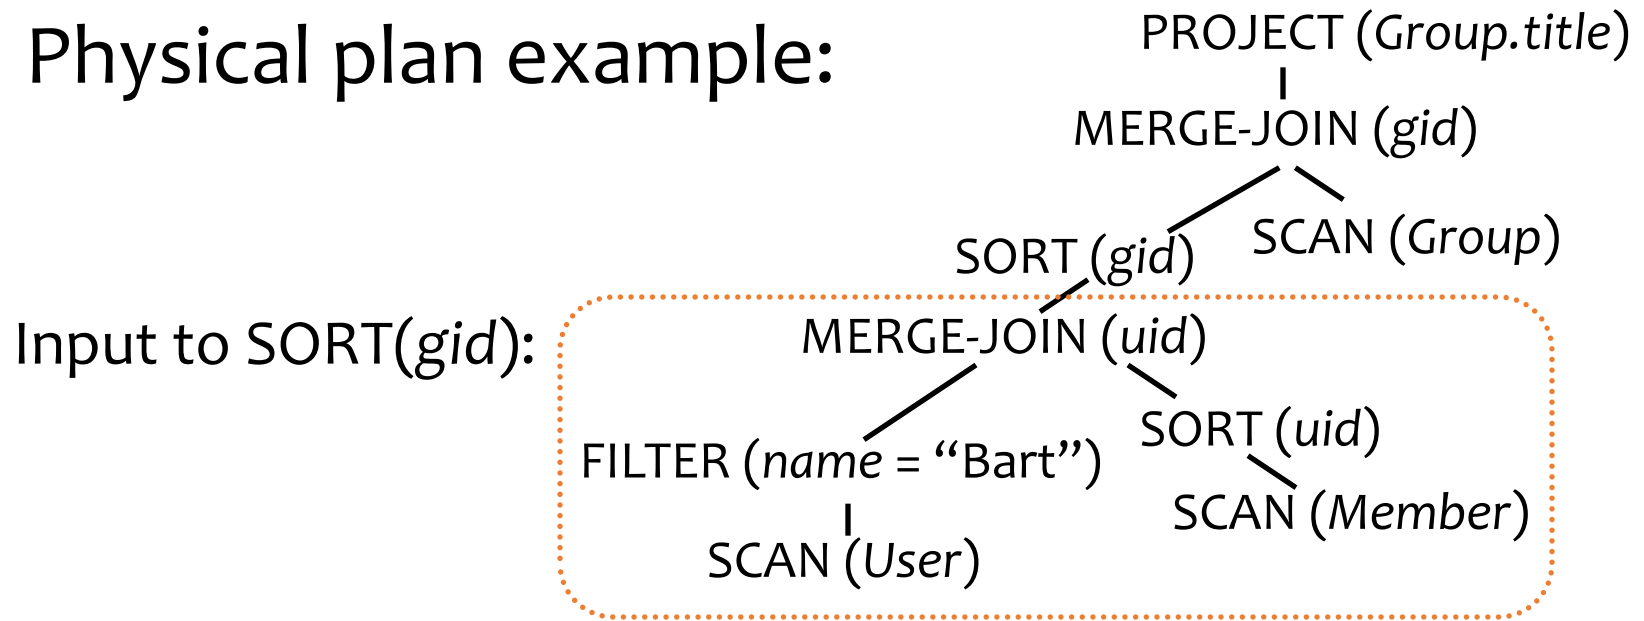

- `SELECT gid FROM Group`  
`WHERE name LIKE 'Springfield%'`  
`AND min_size > (SELECT COUNT(*) FROM Member`  
`WHERE Member.gid = Group.gid);`
- `WITH Supp_Group AS` Process the outer query without the subquery  
`(SELECT * FROM Group WHERE name LIKE 'Springfield%'),`  
`Magic AS` Collect bindings  
`(SELECT DISTINCT gid FROM Supp_Group),`  
`DS AS` Evaluate the subquery with bindings  
`((SELECT Group.gid, COUNT(*) AS cnt`  
`FROM Magic, Member WHERE Magic.gid = Member.gid`  
`GROUP BY Member.gid) UNION`  
`(SELECT gid, 0 AS cnt`  
`FROM Magic WHERE gid NOT IN (SELECT gid FROM Member)))`  
`SELECT Supp_Group.gid FROM Supp_Group, DS`  
`WHERE Supp_Group.gid = DS.gid`  
`AND min_size > DS.cnt;` Finally, refine the outer query

# Heuristics- vs. cost-based optimization

- **Heuristics-based optimization**
  - Apply heuristics to rewrite plans into cheaper ones
- **Cost-based optimization**
  - **Rewrite** logical plan to combine “blocks” as much as possible
  - **Optimize** query block by block
    - Enumerate logical plans (already covered)
    - Estimate the cost of plans
    - Pick a plan with acceptable cost
  - Focus: select-project-join blocks

# Cost estimation

Physical plan example:

- We have: cost estimation for each operator
  - Example: SORT(*gid*) takes  $O(B(\text{input}) \times \log_M B(\text{input}))$ 
    - But what is  $B(\text{input})$ ?
- We need: **size of intermediate results**

# Cardinality estimation

# Selections with equality predicates

- $Q: \sigma_{A=v}R$
- Suppose the following information is available
  - Size of  $R$ :  $|R|$
  - Number of distinct  $A$  values in  $R$ :  $V(R, A) = |\pi_A R|$
- Assumptions
  - Values of  $A$  are uniformly distributed in  $R$
  - Values of  $v$  in  $Q$  are uniformly distributed over all  $R.A$  values
- $|Q| \approx \frac{|R|}{|\pi_A R|}$ 
  - Selectivity factor of  $(A = v)$  is  $\frac{1}{|\pi_A R|}$

# Conjunctive predicates

- $Q: \sigma_{A=u \wedge B=v} R$
- Additional assumptions
  - $(A = u)$  and  $(B = v)$  are independent
    - Counterexample: major and advisor
    - Counterexample:  $A = 10$  and  $A > 30$
  - No “over”-selection
    - Counterexample:  $A$  is the key
- $|Q| \approx \frac{|R|}{|\pi_A R| \cdot |\pi_B R|}$ 
  - Reduce total size by all selectivity factors

# Negated and disjunctive predicates

- $Q: \sigma_{A \neq v} R$ 
  - $|Q| \approx |R| \cdot \left(1 - \frac{1}{|\pi_A R|}\right)$ 
    - Selectivity factor of  $\neg p$  is  $(1 - \text{selectivity factor of } p)$
- $Q: \sigma_{A=u \vee B=v} R$ 
  - $|Q| \approx |R| \cdot \left(\frac{1}{|\pi_A R|} + \frac{1}{|\pi_B R|}\right)$ ?
    - No! Tuples satisfying  $(A = u)$  and  $(B = v)$  are counted twice
  - $|Q| \approx |R| \cdot \left(\frac{1}{|\pi_A R|} + \frac{1}{|\pi_B R|} - \frac{1}{|\pi_A R| |\pi_B R|}\right)$ 
    - Inclusion-exclusion principle

# Range predicates

- $Q: \sigma_{A > v} R$
- Not enough information!
  - Just pick, say,  $|Q| \approx |R| \cdot 1/3$
- With more information
  - Largest R.A value:  $\text{high}(R.A)$
  - Smallest R.A value:  $\text{low}(R.A)$
  - $|Q| \approx |R| \cdot \frac{\text{high}(R.A) - v}{\text{high}(R.A) - \text{low}(R.A)}$
  - In practice: sometimes the **second** highest and lowest are used instead. **Why?**
    - The highest and the lowest are often used by inexperienced database designer to represent invalid values!

# Two-way equi-join

- $Q: R(A, B) \bowtie S(A, C)$
- Assumption: **containment of value sets**
  - Every tuple in the “smaller” relation (one with fewer distinct values for the join attribute) joins with some tuple in the other relation
  - That is, if  $|\pi_A R| \leq |\pi_A S|$  then  $\pi_A R \subseteq \pi_A S$
  - Certainly not true in general
  - But holds in the common case of foreign key joins
- $|Q| \approx \frac{|R| \cdot |S|}{\max(|\pi_A R|, |\pi_A S|)}$ 
  - Selectivity factor of  $R.A = S.A$  is  $1 / \max(|\pi_A R|, |\pi_A S|)$

# Multiway equi-join

- $Q: R(A, B) \bowtie S(B, C) \bowtie T(C, D)$
- What is the number of distinct  $C$  values in the join of  $R$  and  $S$ ?
- Assumption: **preservation of value sets**
  - A non-join attribute does not lose values from its set of possible values
  - That is, if  $A$  is in  $R$  but not  $S$ , then  $\pi_A(R \bowtie S) = \pi_A R$
  - Certainly not true in general
  - But holds in the common case of foreign key joins (for value sets from the referencing table)

# Multiway equi-join (cont'd)

- $Q: R(A, B) \bowtie S(B, C) \bowtie T(C, D)$
- Start with the product of relation sizes
  - $|R| \cdot |S| \cdot |T|$
- Reduce the total size by the selectivity factor of each join predicate
  - $R.B = S.B: \frac{1}{\max(|\pi_B R|, |\pi_B S|)}$
  - $S.C = T.C: \frac{1}{\max(|\pi_C S|, |\pi_C T|)}$
  - $|Q| \approx \frac{|R| \cdot |S| \cdot |T|}{\max(|\pi_B R|, |\pi_B S|) \cdot \max(|\pi_C S|, |\pi_C T|)}$

# Cost estimation: summary

- Using similar ideas, we can estimate the size of projection, duplicate elimination, union, difference, aggregation (with grouping)
- Lots of assumptions and very rough estimation
  - Accurate estimate is not needed
  - Maybe okay if we overestimate or underestimate consistently
  - May lead to very nasty optimizer “hints”

```
SELECT * FROM User WHERE pop > 0.9;  
SELECT * FROM User WHERE pop > 0.9 AND pop > 0.9;
```
- Not covered: better estimation using **histograms**

# Search strategy

# Search space

- Huge!
- “Bushy” plan example:

- Just considering different join orders, there are  $\frac{(2n-2)!}{(n-1)!}$  bushy plans for  $R_1 \bowtie \dots \bowtie R_n$ 
  - 30240 for  $n = 6$
  - Recurrence relation:  $f(n)=f(n-1)*(4n-6)$ , where  $4n-6$  comes from two ways to add the new node to one of  $n-1$  leaves and  $n-2$  internal nodes.
- And there are more if we consider:
  - Multiway joins
  - Different join methods
  - Placement of selection and projection operators

# Left-deep plans

- Heuristic: consider only “**left-deep**” plans, in which only the left child can be a join
  - Tend to be better than plans of other shapes, because many join algorithms scan inner (right) relation multiple times—you will not want it to be a complex subtree
- How many left-deep plans are there for  $R_1 \bowtie \dots \bowtie R_n$ ?
  - Significantly fewer, but still lots— $n!$  (720 for  $n = 6$ )
